THE LANCET

A Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology, Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

VOL. CCXIII.

VOL. II. FOR 1927.

ONE HUNDRED AND FIFTH YEAR.

EDITED BY

SIR SQUIRE SPRIGGE, M.D. CANTAB., F.R.C.P. LOND., F.R.C.S. ENG.,

AND

EGBERT MORLAND, B.Sc., M.B. LOND., M.D. BERNE.

LONDON

PUBLISHED BY THE PROPRIETORS, THE LANCET LIMITED, NO. 423, STRAND, AND NO. 1, BEDFORD STREET, STRAND, IN THE COUNTY OF LONDON, AND PRINTED BY HAZELL, WATSON & VINEY, LD., 52, LONG ACRE, W.C.2.

MCMXXVII.

INDEX TO VOLUME II., 1927.

REFERENCES AND ABBREVIATIONS

Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, and (R. and A.R.) = Reports and Analytical Records.

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

Aachen (Aix-la-Chapelle), 294
Aaron, Charles D., Diseases of the Digestive Organs, 4th ed. (R.), 236
Abattoir society, a model, 1112
Abdominal wall, the fat, method of suturing (Arthur Edmunds), 547
Aberdeen, M.O.H.'s report, 525
Abnormalities, several, in the same patient (M. E. M. Jago), 173
Abortion in Russia and in Germany, 574

THE SUBCUTANEOUS ARSENOBENZOL

SULFARSENOL

Dr. LEHNHOFF-WYLD

THE ORIGINAL FRENCH PRODUCT.

Manufactured by the Laboratoire de Biochimie Medicale, Paris.

Approved for use under the V.D. Regulations, 1916.

Specific in—SYPHILIS in all its stages, YAWS, MALARIA, Gonorrheal Complications, Puerperal Infections.

THE SUBCUTANEOUS OR INTRAMUSCULAR INJECTIONS OF SULFARSENOL IN FRESHLY DISTILLED WATER ARE PRACTICALLY PAINLESS.

A new brochure (Booklet B) containing a résumé of reports and treatment based on recent experience with this product, is now available. A copy will gladly be sent on request.

An Address
ON
VISCEROPTOSIS.

A Contribution to the Discussion at the Meeting of the Association of Surgeons at Glasgow on May 5th, 1927,

BY A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

WITH the spread of civilisation and the improvement in medical knowledge and surgical technique certain diseases tend to disappear, but there are others which are found with increasing frequency and which, indeed, appear to be directly dependent upon the conditions of civilised life. Such a disease is that curious group of symptoms and pathological changes which is spoken of as "visceroptosis"—a name admittedly incomplete, as it only describes one of the many changes. Some 20 or 30 years ago these patients were rarely seen, but to-day they form a large and important section of any abdominal clinic; important in that their symptoms closely resemble those of recognised organic lesions, and that preventive and curative treatment leaves at present much to be desired.

To a certain extent the changes are unquestionably hereditary, and are thus becoming more common in so far as civilisation permits the survival of those who are partly unfit; but in order to obtain the means to preserve the unfit, civilisation demands harder work on the part of the fit, so that they, and especially those on the border-line, are in turn rapidly becoming unfit. In fact, the burden of keeping the unfit is becoming more than the fit can bear. Thus, in ptotic patients environment plays a considerable part in that the stress of life under modern conditions is responsible, especially in women, for many of the changes, and it is, as I hope to show, the combination of the congenital and acquired faults which causes the characteristic symptoms. The pathological changes are widespread, and it is only of recent years that they have been recognised as part of one disease. It will be convenient for descriptive purposes to consider them under the following heads: abnormal mobility and dilatation of the intestines; the presence of accessory membranes; changes in the body structure; altered mentality.

ABNORMAL MOBILITY AND DILATATION OF INTESTINES.

Every case presenting the characteristic symptoms of visceroptosis will, on physical examination or on X ray investigation, show an abnormal mobility of some part of the intestinal tract, but the investigation of this factor is one which is associated with considerable difficulty. There is no true standard of the position and mobility of the portions of the intestinal tract, and it has been shown by many observers that there is a considerable variation in these respects without the presence of any abnormal symptoms. This is especially so in females. McConnell and Hardman, for instance, found that in a series of apparently normal individuals the cæcum and ascending colon were considerably lower in females than in males, but there was also a considerable variation in different individuals. Quain examined 25 nurses with the X rays who had normal gastro-intestinal function; more than half of them had an abnormally low right colon; in two who had never had constipation the hepatic flexure was near the anterior superior spine. But although all persons who have prolapsed stomachs and colons, as found by X ray examination, may not have symptoms, all those who have symptoms are found to have prolapsed and dilated stomachs and colons. The liver is prolapsed, being rotated down to the right rather than directly dropped. The kidneys, and especially the right, are abnormally mobile and frequently dropped. In women the uterus is nearly always retroverted and is frequently prolapsed. The abnormal mobility of the large intestine is in nearly all cases associated with the presence of a mesentery in those areas which normally should have no posterior peritoneal covering. For instance, the duodenum and the cæcum can often be freely withdrawn from an abdominal wound owing to the presence of such a mesentery.

Abnormal dilatation of portions of the intestinal tract is of considerable interest. All cases of true ptosis show dilatation of the stomach or intestine, but unless there is some additional obstructive factor there is never any hypertrophy of the muscular wall. Many adults of both sexes who have reached middle age and are overworked show atony and dilatation of portions of the intestine or of the stomach which causes an acquired ptosis, but such conditions are usually temporary and react well to treatment, so that it is doubtful if they should be regarded as cases of ptosis. Barclay has laid special stress on this point in his X ray investigations of the stomach, and draws a sharp line of distinction between acquired atony and true ptosis. Of greater interest are some of the rarer forms of pronounced dilatation of the intestine. Wilkie has drawn attention to the extreme degrees of atonic dilatation of the duodenum which he has designated as duodenal ileus, and has shown how it is frequently associated with visceroptosis, although personally I believe his view that it is due to compression of the duodenum by the drag of the mesentery is incorrect, and that the dilatation is atonic and is part of the general atony of ptosis. Occasionally cases are seen of extreme dilatation of portions of the large intestine in relatively young people who may complain of constipation alone or of attacks of colicky pain, and it becomes difficult to say whether they should be regarded as advanced degrees of ptosis or mild varieties of Hirschsprung's disease. Such a case is represented in the X rays (Figs. 1 and 2). Probably we shall find in the future that there is no very marked difference between the changes found in ptosis and those of idiopathic dilatation of the colon, and that the attacks of severe pain in the former condition may be due to muscular spasm of a similar nature but in a different situation from that causing the changes of Hirschsprung's disease. It is notable, however, that the dilated portions of the intestine practically never show any hypertrophy, and this, even when there appears to be a definite obstruction. Thus, in my experience, in duodenal ileus the wall is never thickened, as would be expected with obstruction from the mesentery, and the colon in this respect shows a clear distinction from that of Hirschsprung's disease.

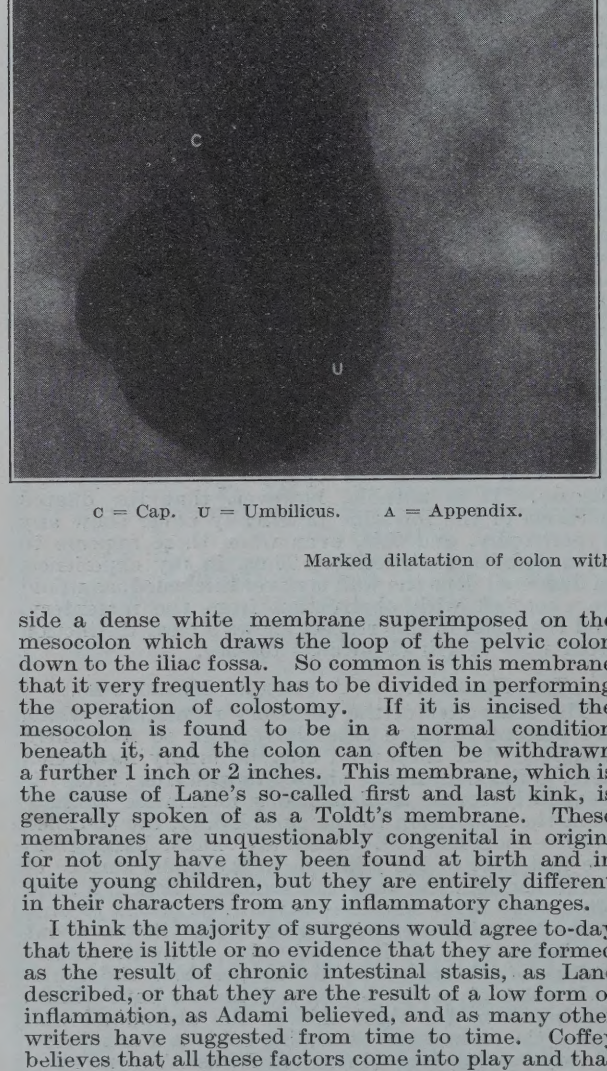
THE PRESENCE OF ACCESSORY MEMBRANES.

The characters of the accessory membranes which are present in these cases have been so frequently described that they need only be briefly mentioned here. Passing from above downwards there is frequently found a filamentous membrane running from the duodenum to the gall-bladder, the so-called cystico-duodenal fold. There are similar bands from the first part of the jejunum to the under surface of the mesocolon, the mesocolic bands. There is a band often more dense and fibrous than the others passing from the antimesenteric border of the ileum, about 2–6 inches from the ileocæcal valve, along the under-surface of the mesentery to the posterior abdominal wall which gives rise to the well-known Lane's kink. Passing from the right side of the abdominal wall across the cæcum and ascending colon is a membrane of very varying degree known as Jackson's membrane. In the less advanced cases it is present only as a small band across the cæcum and involving an atrophic appendix, while in the more advanced degrees it forms a wide curtain, often continuous above with the gall-bladder and hepatic flexure, when it is known as the cystico- or hepatico-colic fold. In the middle portion it runs right over the ascending colon, and may even fuse this portion of the intestine with the commencement of the transverse colon, in which case

it is clearly a continuation of the great omentum, while below it enfolds the cæcum in a thin and voluminous bag. Similar membranes are found at the splenic flexure running from the termination of the transverse colon to the commencement of the descending colon, so that these two portions of the intestine lie parallel and are fixed above to the spleen, these membranes being spoken of as Payr's membranes. In the loop of the pelvic colon there is on the outer side a dense white membrane superimposed on the mesocolon which draws the loop of the pelvic colon down to the iliac fossa. So common is this membrane that it very frequently has to be divided in performing the operation of colostomy. If it is incised the mesocolon is found to be in a normal condition beneath it, and the colon can often be withdrawn a further 1 inch or 2 inches. This membrane, which is the cause of Lane's so-called first and last kink, is generally spoken of as a Toldt's membrane. These membranes are unquestionably congenital in origin, for not only have they been found at birth and in quite young children, but they are entirely different in their characters from any inflammatory changes.

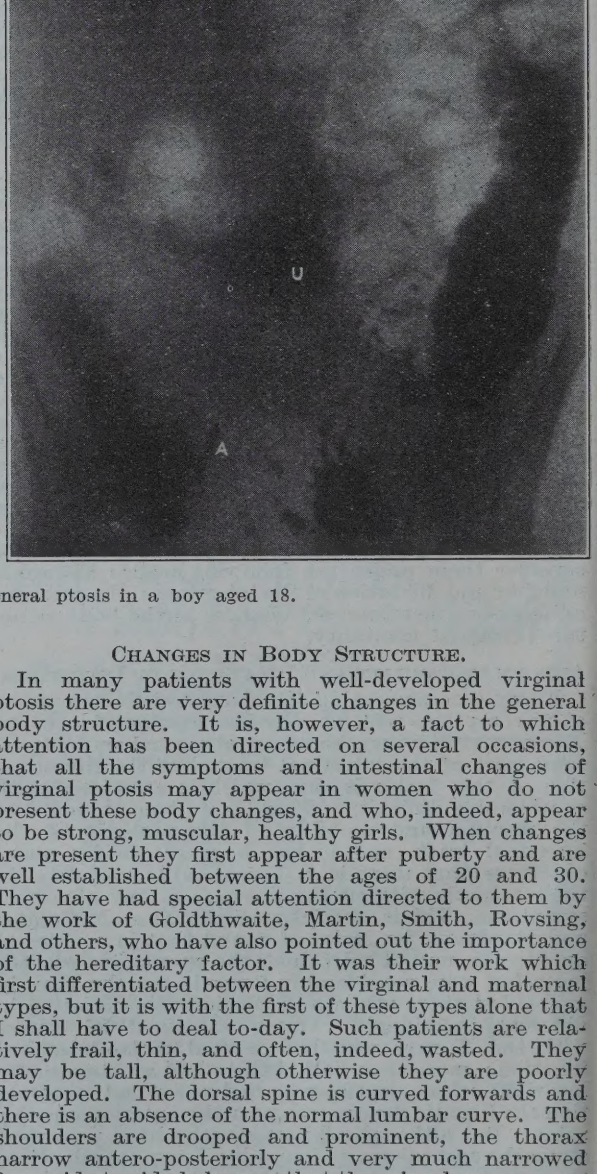
I think the majority of surgeons would agree to-day that there is little or no evidence that they are formed as the result of chronic intestinal stasis, as Lane described, or that they are the result of a low form of inflammation, as Adami believed, and as many other writers have suggested from time to time. Coffey believes that all these factors come into play and that some of the membranes are congenital and represent anomalous fœtal developments, whereas others are inflammatory and the widespread membranes arise as Lane has described. My own experience has strongly favoured the view of their congenital origin, for it will be seen that among my cases which have been subjected to operation 22 were young people under the age of 20, in whom these acquired factors could hardly have been at work. Some degree of accessory membrane formation is extremely common, and in fact in over 50 per cent. of women they may be found in some form or other. It is only when they are present to an excessive degree that they can be regarded as pathological. It is also becoming evident as one is gaining wider experience that there is a definite hereditary factor in these cases, a high percentage of girls with virginal ptosis having mothers who have suffered from the same condition.

FIG. 1.



C = Cap. U = Umbilicus. A = Appendix.

FIG. 2.



Marked dilatation of colon with general ptosis in a boy aged 18.

CHANGES IN BODY STRUCTURE.

In many patients with well-developed virginal ptosis there are very definite changes in the general body structure. It is, however, a fact to which attention has been directed on several occasions, that all the symptoms and intestinal changes of virginal ptosis may appear in women who do not present these body changes, and who, indeed, appear to be strong, muscular, healthy girls. When changes are present they first appear after puberty and are well established between the ages of 20 and 30. They have had special attention directed to them by the work of Goldthwaite, Martin, Smith, Rovsing, and others, who have also pointed out the importance of the hereditary factor. It was their work which first differentiated between the virginal and maternal types, but it is with the first of these types alone that I shall have to deal to-day. Such patients are relatively frail, thin, and often, indeed, wasted. They may be tall, although otherwise they are poorly developed. The dorsal spine is curved forwards and there is an absence of the normal lumbar curve. The shoulders are drooped and prominent, the thorax narrow antero-posteriorly and very much narrowed from side to side below, so that there is a long, narrow, epigastric angle. When standing erect the upper abdomen is flattened and the lower protruberant and flabby. The narrowness of the abdomen and the lower thorax gives a curious picture, as though the patient had a pelvis which was too big for her body. It is

also the narrowing of the lower thorax which to a large extent gives rise to the displacement of the abdominal viscera, for in a well-established case it is evident that the viscera could not be replaced owing to this narrowness. In addition to this, there is very often general muscular weakness, and there may be a certain amount of genu valgum or flat-foot.

With such a body-change the hereditary influence is often strongly in evidence. Briggs has worked out a series of 128 members of 23 families all descended from a veteran of the American Civil War. Of the 128 members, 64 were affected with ptosis, thus agreeing with the Mendelian principles. Rovsing has shown, however, that similar changes may be due to external interference with normal development, which will not begin to be active until after the onset of puberty. The fact that some patients with symptoms of visceroptosis do not show these changes, but are well-developed, muscular girls, while others show a marked "ptosis habitus" was for a time difficult to understand, but has been made clear by Sherrington's work, which has shown that voluntary muscular movements are quite distinct from those of postural activity, and may indeed possibly be carried out by separate muscular fibres. Thus it is that patients who have strong and well-developed voluntary muscles may have a poor postural tone, and it is indeed noticeable to-day that many girl athletes with a well-developed bony frame and muscles have an extremely poor stance and hold their bodies very badly. It is also probable that girls who are occasionally seen with a marked "ptosis habitus" and no symptoms have, in spite of their deformity, developed good postural tone.

CHANGES IN MENTALITY.

In the advanced stages these patients usually show an abnormal mentality which is one of the chief obstacles to satisfactory treatment. Their outlook on life is miserable and despondent, their whole attention being concentrated upon their symptoms. For this reason their response to treatment is difficult to estimate, for even if relieved of their abdominal symptoms they complain of difficulties elsewhere. Their symptoms, in fact, develop a very definite functional or hysterical basis. Although they are despondent and miserable, they rarely become suicidal, and it is also noticeable that although they expend a great deal of energy in seeking advice, they rarely have sufficient application to follow the lines of treatment that are given to them. It is difficult to determine what is the relationship of these mental changes to the original disease, for it is possible that any patient subjected to long-continued physical pain would develop such a mentality, but on the other hand, as Bankart has pointed out, it may be congenital poor mentality of this sort which is so largely responsible for the absence of postural tone. Postural activity is acquired in early life, a good body position being only maintained at first by irksome voluntary effort which later becomes unconscious and reflex. A man of poor postural tone who is drilled in the army at first finds it extremely difficult to develop a correct posture, but after a time it is maintained without thought or apparent effort. A patient with the poor mentality above described is just such a one who would be unable or unwilling to go through the irksome early stages of obtaining postural activity. Mental fatigue would arise early, and prolonged effort would be impossible. A poor mentality is probably, therefore, part of the inherited disability.

ÆTIOLOGY.

Virginal ptosis is a condition which is much more common in women. In my own series of 441 cases, 340 were found in women, and even these figures are probably not sufficiently high, for the typical clinical case where the symptoms begin in relatively early life and persist for many years is found almost wholly in women, although among some of the more poorly-developed younger men of to-day there is found the characteristic body structure and early and long-persistent symptoms which are so characteristic in the female. The majority, however, of men in whom ptosis, and only ptosis, is found at operation are patients who have a normal body structure and who have not developed any symptoms until considerably later in life. Thus, the age-incidence of the individual patients among women was as follows:—

10–20 ..	22	30–40 ..	108	50–60 ..	89
20–30 ..	66	40–50 ..	87	60–70 ..	18

A large number of them thus having sought advice between 20 and 40, and only 37 per cent. of them being between the ages of 40 and 60. In the males, on the other hand, no cases were seen under 20, and 50 per cent. of them were between 40 and 60, the actual figures being:—

20–30 ..	13	40–50 ..	30	60–70 ..	3
30–40 ..	35	50–60 ..	28		

In many of them the onset of symptoms seems to be definitely due to hard work at an age when the body is beginning to tire, and, indeed, men of this age are often unwilling to admit that they cannot work as hard as formerly, and, in order to convince themselves that they can, actually increase their work. Such cases on examination not only show the absence of the general characters of ptosis, but rapidly improve with rest and modification of their work, so that it is doubtful indeed whether they should be included as cases of ptosis, but should not rather be regarded as examples of a temporary atony.

FIG. 3.

Prolonged spasm of transverse colon; operation revealed genera ptosis only.

It is curious that with this very much greater preponderance of the female sex, the condition should often have been regarded as a predisposing factor to the development of gastric and duodenal ulceration, although these lesions are much more common in men. In my own series of 1003 gastric and duodenal ulcers, 761 were males and only 242 females. It is perfectly true that there is often very considerable difficulty in the diagnosis of a case of visceroptosis

from a chronic gastric or duodenal ulcer, but it is relatively uncommon to find the two conditions associated. In my own series there have been 61 patients who have had both ptosis and ulceration; thus, with 1003 gastric ulcers ptosis it is only found in 6·09 per cent. The one type of chronic ulcer which is so frequently found with ptosis and upon which the ptosis unquestionably acts as a predisposing factor is hour-glass stomach, a condition which is limited to the female. In my own 49 cases of hour-glass stomach, visceroptosis was noted as being present in 24. If these and the cases of acute ulceration are deducted from the total it leaves 948 cases of ulcer, 34 of which showed ptosis, a percentage of 3·58. In the same way, if the cases of ptosis are considered, the 441 showed 61 cases of ulcer, a percentage of 13·83. If the 27 cases of hour-glass and acute ulcers with ptosis are deducted from this group also, it leaves 414 cases, with 34 having chronic ulcers, a percentage of 8·21, and this percentage is no higher than would be expected as a mere coincidence.

A consideration of the pathological and ætiological evidence, therefore, makes it clear that the clinical picture of visceroptosis is a combination of several factors. As a congenital fault there is the presence of increased mobility and membrane formation, with possibly a rather poor mentality and a tendency for bad body development. The mobility and membrane formation are seen in so large a proportion of the population that in themselves they can hardly be considered an abnormality, and if present alone will give rise to no symptoms, thus accounting for the fact that membranes and abnormal mobility are often found at operation in apparently healthy people. An inherited mental and physical weakness can, however, only be an accessory factor, otherwise the condition would probably be as common in men as in women, and we must rather look for some error in environment to explain why the symptoms are found three times as commonly in the female. Under modern conditions the training of young girls, and especially the training of their static muscles, is insufficient, and a certain number of them therefore develop a poor postural tone and a bad body structure. Should their intestines show no accessory membrane formation they will develop no symptoms, and this even if, owing to the weakness of the abdominal muscles, there is a profound degree of ptosis. It has long been noted that patients may be seen with an extreme degree of visceral ptosis who yet have no symptoms. This is especially so in the cases of maternal ptosis, where a patient who has had many children in rapid succession may have practically no abdominal wall left. If, however, they have the accessory membranes, symptoms will develop shortly after puberty, when the body changes become evident. It is because women are so much more the subjects of poor postural muscular development that the disease is so much more frequently seen in them than in men. In men the postural muscles are better developed, and symptoms do not appear until there is a loss of tone with the commencing weakness of late middle age. It is necessary not only for the intestines to drop, but they must be irregularly kinked by the bands and membranes which are present as a congenital deformity. There is possibly yet another factor, for no hypertrophy of the muscular coat can be demonstrated proximal to the bands such as would be expected if they were causing a mechanical obstruction. The pain is, however, spasmodic in type, and X ray investigations very frequently show irregular areas of spasm both in the stomach and colon (Fig. 3). The severity of the pain and its spasmodic nature is somewhat alike that found with angina pectoris and certain spasmodic arterial lesions, and is suggestive that it may be due to over-action of the sympathetic supply.

[*The concluding portion of this address dealing with Symptoms and Treatment will appear in our next issue.*]

An Address

ON

THE LAW AND ETHICS OF MEDICAL CONFIDENCES.

Delivered before the Medico-Legal Society on June 23rd, 1927,

BY LORD RIDDELL.

IN both law and ethics medical confidences are regarded as sacred with certain exceptions. The question is what the exceptions are. When may the doctor tell; when should he tell; and when must he tell? On two of these points there is considerable difference of opinion in legal and medical circles.

The rule as to medical secrecy arises out of the fiduciary relationship which exists between the doctor and his patient, analogous to that between solicitor and client. This doctrine of fiduciary relationship dates back to the time of Hippocrates, and has been recognised by the English courts in several cases relating to pecuniary transactions between doctors and their patients (Dent *v.* Bennett [1839] 4 My. and Cr. 48 R.R. 94; Billage *v.* Southee [1852] 9 Ha. 534; Mitchell *v.* Homfray [1881] 8 Q.B.D. 587).

ENGLISH AND SCOTTISH LAW.

In England there is a curious absence of direct authority as to the doctor's liability for failing to keep his patients' affairs secret. This is greatly to the credit of doctors as a race. Had they been unduly communicative to the detriment of their patients no doubt they would have found themselves in the Law Courts. There are, however, analogous cases which show that the courts regard professional secrecy as a grave moral duty which will be enforced, either because disclosure would be a breach of trust and confidence, or because secrecy is an implied term of a contract for professional or confidential services. The duty has been enforced against solicitors; see, for instance, Taylor *v.* Blacklow (1836) 3 Bing N.C. 235; against accountants, see Weld Blundell *v.* Stephens (1920) A.C. 956; and against bankers, see Tournier *v.* National Provincial Bank (1924) 1 K.B. 461. Lord Justice Scrutton's judgment in the latter case contains the following dictum:—

> I have no doubt that it is an implied term of a banker's contract with his customer that the banker shall not disclose the account, or transactions relating thereto, of his customer except in certain circumstances. This duty equally applies in certain other confidential relations, such as counsel or solicitor and client, or doctor and patient. The circumstances in which disclosure is allowed are sometimes difficult to state, especially in the case of a medical man.

The Court refrained from expressing an opinion on the degree of latitude allowed to a doctor in disclosing professional confidences.

In the Duchess of Kingston's case (1776) Lord Mansfield remarked that if a surgeon were voluntarily to reveal medical secrets he would be guilty of a breach of honour, and according to Mr. Justice Vaughan (see Taylor *v.* Blacklow at p. 249) "the law is never better employed than in enforcing the observance of moral duties." Therefore, notwithstanding the absence of direct authority, we are entitled to assume that a doctor would be legally liable for damages sustained by his patient owing to the wrongful disclosure of the patient's confidences.

In Scotland the law is more definite. The case of A. B. *v.* C. D. (1851) 14 D. 177, decided that a doctor might be sued by his patient for a breach of confidence. As this is the only case I can trace in which a medical man has been held liable for a breach of medical confidence it may be well to state the facts. The wife of plaintiff, an Elder of the Established Church, had a child six months after marriage. The kirk session demanded an explanation, including medical testimony. Thereupon plaintiff instructed defendant, a local

doctor, to examine the child and report. Defendant reported in writing that the child had been conceived before marriage, and sent a copy of the report to the minister, who handed it to the kirk session, who treated it as a confession of antenuptial fornication, declined to accept plaintiff's resignation, and ejected him from the kirk. The judges held that there was an implied contract against voluntary disclosure. Lord Fullerton added: "The obligation may not be absolute. It must yield to the demands of justice, if disclosure is demanded in a competent court. It may be modified perhaps if the disclosure is conducive to ends of science—though even there concealment of individuals is usual. But that a medical man, consulted in a matter of delicacy of which the disclosure may be most injurious to the feelings and possibly the pecuniary interests of the patient, can gratuitously and unnecessarily make it the subject of public communication without incurring any imputation beyond what is called a breach of honour, and without liability to a claim for redress in a court of law, is a proposition to which, then thus broadly laid down, I think the court will hardly give their countenance."

In the later case of McEwan *v.* Watson (1905) 12 Scottish Law Times 248 and 599, 13 S.L.T. 340, the House of Lords, on a Scottish appeal, declined to express any opinion as to the right of action. They decided the case on the ground that it could not be actionable to disclose secrets in the witness-box if the practitioner were called as a witness, or even to inform counsel and solicitors of the evidence he was prepared to give.

In some European countries, France and Germany, for instance, the disclosure of medical secrets is a criminal offence. In Germany the rule includes midwives and apothecaries.

The legal position in England may be stated thus, although in some respects not altogether free from doubt:—

1. A doctor, being in a fiduciary capacity, must preserve his patients' confidences unless relieved from the obligation by some lawful excuse.

2. Legal compulsion or the patient's consent are lawful excuses, and the performance of a moral or social duty may also be a justification. Protection of the doctor's interests may also justify disclosure.

3. There is no legal privilege for medical confidences. If called as a witness a doctor must answer such questions as may be put to him by the court.

4. A doctor shares with other citizens the duty to assist in the detection and arrest of a person who has committed a serious crime.

FIRST PROPOSITION.

"A doctor, being in a fiduciary capacity, must preserve his patients' confidences unless relieved from the obligation by some lawful excuse."

This will not be disputed, at any rate on ethical grounds. Every doctor admits that he must preserve his patients' confidences. It is true that the Hippocratic oath is rather hazy. It says: "Whatsoever I shall see or hear in the course of my profession as well as outside my profession in my intercourse with man if it be what should not be published abroad I will never divulge, holding such things to be holy secrets." This amounts to little more than a general declaration against gossiping. The practitioner is left to determine for himself what things in connexion with his profession or not in connexion with his profession "ought not to be spoken abroad." Perhaps an explanation is provided in Hippocrates' Essay on Decorum, in which he warns the practitioner not to gossip to laymen, as gossip may cause criticism of his treatment! But, as stated, the profession recognise that medical confidences are sacred. A breach of the rule may result in serious consequences. Not only may the doctor render himself liable in damages, but he may also be censured by the General Medical Council for unprofessional conduct. It must be confessed that many doctors are not as reticent as they might be. A surgeon who spends his days in removing appendices or gall-stones, or in performing hysterectomies does not perhaps realise that his patients may desire to preserve the secrets of their truncated anatomies. It must be admitted, however, that many patients, as we know to our cost, are proud to descant at large upon their illnesses, and in particular upon their achievements on the operating table. In many cases the doctor is only echoing his patient. Notwithstanding occasional lapses, doctors are entitled to claim with justice that professional confidences regarding vital matters, such as venereal disease, what I may call unofficial pregnancies, attempted abortions, and the like, are rarely divulged. If the doctor gossips he only does so in connexion with matters he regards as immaterial. If he falls from grace he offends through inadvertence or good-humoured loquacity. Perhaps when his offence is pointed out he salves his conscience by the reflection that if he has sometimes been indiscreet, he has, on the other hand, told many lies and exercised many economies of truth to save a patient's reputation. At the same time, if medical advertising were permitted, I am sure that a sign reading "Dr. Blank is a regular oyster. He never talks about his patients," would be a valuable recommendation to the laity. Some doctors think they are entitled to disclose their private patients' secrets to other medical men or to their students. This is a mistake. Medical freemasonry does not justify such disclosures. The symptoms and treatment may be stated, but not the patient's name.

The disposal of doctors' case-books raises an interesting point. Is the doctor entitled to sell them, and what are the responsibilities of the purchaser, and what are those of the doctor's executors? Many years ago I bought a doctor's case-book in a secondhand book shop for sixpence. Evidently it had been sold as waste paper or as part of a library. I suppose, strictly speaking, a doctor or his executors are not entitled to part with his case-books containing professional secrets, and that in strictness the books should be destroyed. But in these days when it has become the practice to dig up the medical histories of the departed, the destruction of the case-books of leading practitioners might rob future generations of much interesting information. Whether these revelations are justifiable is another matter. Evidently they strike a blow at the foundations of medical secrecy.

SECOND PROPOSITION.

"Legal compulsion or the patient's consent are lawful excuses, and the performance of a moral or social duty may also be a justification."

This proposition raises more difficult questions. Legal compulsion is admittedly a lawful excuse, whatever it may be from the point of view of medical ethics. But when we come to the performance of a moral or social duty, we are faced with serious problems. Let us take some hypothetical cases:—

(*a*) A family doctor is consulted by a husband or wife suffering from syphilis. Is the doctor justified in warning the other spouse to refrain from marital intercourse?

(*b*) A patient who is suffering from lunacy, venereal disease, or tuberculosis in a severe form, tells his doctor that he is engaged to be married, and although the doctor warns him not to do so, insists on proceeding with the ceremony. Is the doctor justified in warning the other party and his or her parents?

(*c*) The family doctor is consulted by an unmarried daughter of the house who proves to be pregnant. Is the doctor entitled to tell her mother?

(*d*) A doctor is consulted by a wife who has procured an abortion and who is seriously ill. Is the doctor entitled to inform the husband?

(*e*) A doctor is called to attend a domestic servant, perhaps a cook or a nurse, and finds she is pregnant or suffering from some contagious skin disease. Is he entitled to tell the mistress?

(*f*) A doctor is consulted by an engine-driver who thinks he is suffering from nervous exhaustion. The doctor diagnoses G.P.I. and tells the patient he is not fit to drive. The patient disagrees. Is the doctor justified in reporting the matter to the railway company?

(*g*) A patient shows signs of incipient insanity and talks dimly of suicide. Is the doctor entitled to warn his relatives and friends?

(*h*) A doctor is consulted by a hairdresser suffering from barber's itch. He warns him not to pursue his calling until cured. The next day he sees him at work. Is the doctor entitled to warn the man's master?

(*i*) The doctor at a V.D. clinic is consulted by a shop-girl suffering from a most contagious form of gonorrhœa. The patient lives in a hostel belonging to the store where she works. The doctor tells her she should leave the hostel as she may infect her companions. She refuses. Is the doctor entitled to warn her employers?

What is the doctor's position in such cases? Has he a moral or social duty justifying and perhaps necessitating disclosure? If he has, would it be a defence in the Law Courts?

What would be the position of a solicitor faced with similar problems? It is easier to put these questions than to answer them. In this country there is no direct decision on the subject, but an interesting Austrian case was reported in THE LANCET, April 16th, 1921. A V.D. specialist who was sitting in a public bath pool saw a young man whom he had recently treated for a syphilitic sore about to enter it. The physician objected, and as the young man persisted, he reported him to the attendant, who refused to allow him to bathe. Thereupon he brought an action against the doctor for breach of professional confidence. The court dismissed the case on the ground that the doctor had acted in the interests of the community. This admirable decision, which, of course, has no validity in this country, corresponds with views expressed by English judges in relation to the professional privilege of a solicitor. In the Queen *v.* Cox and Railton (1884) 14. Q.B.D 153, the question was whether communications by a client to his solicitor regarding a contemplated fraud could be given in evidence by the solicitor without the client's consent. The Court held that the evidence was admissible, and quoted with approval a passage taken from the report of an earlier case, "no private obligations can dispense with the universal one which lies on every member of society to discover every design which may be formed contrary to the laws of society to destroy the public welfare." The courts are, however, vigilant in enforcing professional secrecy. In Weld-Blundell *v.* Stephens (1920) A.C. 956, the Law Lords and the judges in the Court of Appeal all agreed that there is no reason founded on public policy or any other ground why an agent, in that case an accountant, should be at liberty to disclose a private wrong committed by his principal. This rule had already been laid down in 1836 in Taylor *v.* Blacklow, already quoted. In Taylor's case a solicitor, acting for both parties in a mortgage transaction, was held liable for disclosing to the proposed mortgagee a defect in the mortgagor's title. In the Weld-Blundell case a distinction was, however, drawn by the judges in the Court of Appeal between communications regarding a wrong about to be committed and one committed already. Lord Justice Bankes put two instances. (1) A person tells his doctor that he intends to commit suicide; (2) a person charged with attempting suicide confesses to his solicitor that he did make the attempt. To protect the patient the doctor would be entitled to disclose the confidence; the solicitor would not be justified in revealing the confession. In both the Weld-Blundell and Tournier cases the judges agreed that disclosure of a confidence would be justified when there is a duty to the public to disclose. The point was elaborated by Lord Justice Bankes, who said: "A contract to keep secret communications as to the proposed commission of a crime or as to the proposed commission of a civil wrong upon an individual may well be considered as an illegal contract, and the duty to the public to disclose the criminal or illegal intention may properly be held to override the private duty to respect and protect the client's confidence."

It is obvious that when called upon to deal with cases similar to those suggested the doctor is required to navigate an uncharted sea. Happily they are rarely presented in the crude form indicated in my hypothetical instances. The patient is usually prepared to coöperate with his medical adviser. But for present purposes we must face the issue. Before doing so I must point out (1) that when a doctor is employed by "A" to examine and treat "B"; for instance, when a medical man is called in and paid by a mistress to examine and treat a domestic servant—the doctor is apparently entitled to make a report to the person employing him. Weldon *v.* Winslow, the *Times*, March 14th to 19th, 1884. An action for libel: A husband asked a medical man to see his wife and report on her mental condition. He reported that she was insane. Held a privileged communication. Presumably it could not have been privileged if a breach of professional confidence. (2) That the position of a family doctor may differ from that of one consulted *ad hoc*. The confidential relationship of the family doctor may justify disclosures that would otherwise be improper. The law of libel and slander recognises that a family solicitor has special duties and privileges regarding the communication of information to his client (Davis *v.* Reeves, Ir. C.L.R. 79). Therefore, by what may be called a double analogy, the special position of the family doctor may well be a factor to be considered. (3) That a doctor attending an infant may be entitled to communicate with his parent or guardian. (4) That the position of a hospital patient differs from that of a private one, inasmuch as there is no contract between the doctor and the patient. Such a patient's rights to secrecy are not well defined, but it is conceived that the medical staff are under obligation to the patient not to disclose matters of delicacy, at any rate outside the institution.

In the French code the director of a hospital is specially prohibited from disclosing professional secrets relative to the safety of patients or family honour.

I now come to the general question of what should the doctor do when he perceives that grievous injury may result to a third party or parties if he refrains from making a communication that may involve the disclosure or partial disclosure of a professional confidence. A distinguished legal friend of mine has suggested that in certain cases disclosures may be justified on the ground that the object is to prevent the patient from doing a wrongful act. There is much to be said for this argument. The spread of infectious disease, for example, may give rise to criminal and/or civil liability. R. *v.* Vantandillo (1815) 4 M. and S. 73. Boardman *v.* Boardman (1866) 1 P. and M. 233. R. *v.* Clarence (1889) Q.B.D. 22. Clerk and Lindsell on Torts 7th edition 495. Stephen's Digest of Criminal Law, 6th edition, 147. Lord Stowell described the communication of venereal disease as "an injury of a most malignant kind." Mr. Justice Hawkins described it as "an abominable outrage" and "an atrocious barbarity." The doctor may therefore claim that in certain cases he is entitled to take reasonable steps to protect the patient against himself. He may also claim, relying on the dicta in Cox *v.* Railton, Weld-Blundell and Tournier, that it is a public duty to prevent wrongful acts and that there are occasions when the duty imposed by a professional relationship should be subordinated to the higher duties of common humanity. The terrible consequences to innocent persons of secrecy in the hypothetical cases of the syphilitic husband or wife, the diseased fiancé, the syphilitic cook or nurse, the hairdresser with barber's itch, the shopgirl suffering from gonorrhœa, or the lunatic engine-driver are matters deeply concerning the public welfare. Disclosure to avoid such consequences is justifiable and perhaps obligatory on both legal and ethical grounds. But admitting this, the practical question still remains to be answered: What should the doctor do? If he gives the warning he may get no thanks; he is certain to incur the serious displeasure of his patient, and he may find himself faced with legal proceedings. On the other hand, his conscience may worry him if he stands by and allows an innocent person or persons to run a serious risk which might be prevented by a word of warning. Moreover, in some cases if he remains silent he may run the risk of incurring public or private odium and censure. No practical rule can be laid

down. It all depends on the individual and the particular case.

THIRD PROPOSITION.

"There is no legal privilege for medical confidences. If called as a witness a doctor must answer such questions as may be put to him by the Court."

This has been decided in many cases. The Duchess of Kingston's case (1776) 20 How. St. Tr. 572 et seq. R. *v.* Gibbons (1823) 1 C. and P. 97. Wheeler *v.* Le Marchant (1881) 17 Ch. D. 681. The subject is highly controversial. Strong objection has been raised by doctors to answering in the witness-box questions involving a disclosure of professional confidences. The claim is that such confidences are or should be privileged in the same fashion as communications between solicitor and client. This view has been held not only by medical men, but by distinguished lawyers. For instance, the learned author of "Best on Evidence," describes the rule as "harsh in itself, of questionable policy, and at variance with the Code Pénal in France and the Statute Law in some of the United States of America." (See p. 560, 11th edition.) It is claimed by some medical men who object to the rule that communications made to spiritual advisers are protected from disclosure in courts of justice. This is inaccurate. (See cases quoted in Best, p. 561.) It may also be pointed out that the claim to spiritual privilege is based on legal grounds which have no application to the medical profession. It is argued that communications made to priests and other ecclesiastics were entitled to privilege under the Canon Law and that, although repealed, these particular canons are still part and parcel of the existing Common Law.

There also seems to be some misapprehension in medical circles as to the privilege accorded to communications between solicitor and client. The privilege is that of the client and not of the solicitor, who himself has no privilege (Taylor on Evidence, 16th edition, Section 911, and cases there quoted). Except as mentioned later, the solicitor must not disclose professional communications in the witness-box unless with the consent of his client, but they must be revealed if the client so desires. Those who claim privilege for medical communications also labour under the misapprehension that privilege attaches to communications made by a client for a fraudulent or criminal purpose, as, for instance, if a solicitor were questioned as to the most skilful mode of effecting a fraud.

The case for medical privilege is put thus. Medical confidences are sacred. Therefore they should be treated as such in all circumstances. Medical efficiency is a public necessity. To secure it patient and doctor must be assured that their communications will not be disclosed. Truth in litigation may cost too dear. In the interests of the community at large it is more important to maintain the sacred character of confidential relationships than to secure accuracy in a few law cases. On the other side it is claimed that it is undesirable to increase the limitations on evidence, that the existing system has caused no injustice or inconvenience, that there has been no public protest against it, that there is no evidence that fear of disclosure deters patients from confiding in their medical advisers, that the confidences of criminals could not properly be subject of privilege and that, eliminating such confidences, there are but few occasions on which disclosures detrimental to the patient are required. A typical case will display the respective points of view. A woman whose husband has been abroad 12 months consults a doctor as to her pregnancy. She has a spontaneous miscarriage. Her husband returns and lives with his wife. Some months later he hears that she had been unfaithful. He takes proceedings in which the doctor is subpœnaed as a witness. The doctor is asked what he treated the wife for. According to medical critics of the existing law it is improper that the question should be answered. The woman was compelled by her condition to consult a doctor. Is it fair and right that by so doing she should involuntarily provide evidence of adultery? Had she gone to a solicitor for advice as to the legal position arising from her indiscretion her communications with him would have been protected. It is an *a fortiori* case that communications with her doctor should receive similar protection. According to their opponents it would be an injustice if the husband were debarred from proving his case. Any change in the law would require to be made by Statute and there is little chance that Parliament would alter the existing rule. Any such alteration would almost certainly be vigorously opposed by the Law Lords and judges. The whole tendency of legislation for many years past has been to simplify the law of evidence and to remove restrictions which prevent the whole story from being disclosed to the court. Consequently it is extremely unlikely that Parliament would be prepared to add to such conventions as still exist. On balance it seems most undesirable that fresh privileges should be created which may have the effect of obscuring the truth. Those who wish to explore this subject further should read Lord Birkenhead's brilliant article, "Should a Doctor Tell?" "Points of View, Vol. I."

FOURTH PROPOSITION.

"A doctor shares with other citizens the duty to assist in the detection and arrest of a person who has committed a serious crime."

The law is clear. (See Russell on Crimes, 8th edition, Vol. I., p. 130.) A person who, knowing a felony to have been committed by another, relieves, comforts, or assists the felon, is an accessory after the fact. I suppose that binding up a murderer's wounds and sending him on his way rejoicing might suffice. Hale, however, expresses the view that a surgeon can safely attend a felon, but if he fails to report the felony to the police he will be guilty of misprision of felony. (I. Hale 332.) Misprision of felony consists in concealing or procuring the concealment of a felony known to have been committed. It is sufficient to neglect to inform the police. The offence, however, seems to be almost obsolete and it may be doubted whether any prosecution is likely to be instituted in practice. It is obvious that it is no part of the duty of a doctor to act as a private detective. It is also plain that when, in the course of his professional duties, he has reason to think that a serious crime has been committed, he is bound to help to bring the offender to justice although this may involve the arrest of his patient. For instance, suppose that during the hue and cry for the trunk murderer a doctor had been consulted by a man suffering from injuries which he admitted were sustained when struggling with a woman who had been killed in the encounter, obviously it would have been the doctor's duty to inform the police. Furthermore, no alleged ethical rule could have justified him in shielding such a criminal from justice. Plain cases of this kind require no further comment. Law and ethics demand prompt and decisive action. Indeed, even in the absence of a confession by the criminal, it would be the duty of the doctor to warn the police if he thought the circumstances suspicious. If the patient were innocent he would not suffer. If he were guilty he would get no more than his deserts.

Mr. Justice Hawkins remarked in the Kitson case (1896): "There might be cases when it is the obvious duty of a medical man to speak out, and it would be a monstrous thing for a medical man to screen a person coming to him with a wound which it might be supposed had been inflicted in the course of a deadly struggle." In the Pritchard poisoning case the doctor stated that when he first saw deceased he was under the impression she was being poisoned. Commenting on this the judge said that it was inconsistent with the doctor's duty as a medical man and a citizen to keep this information to himself. He added: "I care not for professional etiquette or rule; there is a rule of life and a consideration far higher than these, and that is the duty of every citizen and of every right-minded man to his neighbour, to prevent the destruc-

tion of human life and in that duty I cannot but say that the doctor failed." Difficult questions, however, arise as to crimes of certain classes such as abortion. If a woman admits to an abortion is the doctor bound to go to the police, and if not is he justified in doing so? In the Kitson case Mr. Justice Hawkins doubted whether a medical man would be justified, "for such a thing would be monstrous cruelty." Too much attention must not be paid to this dictum as the point did not arise for decision. More reliance may be placed upon Mr. Justice Avory's charge to the grand jury at Birmingham in December, 1914 (49 L.J. 713). A woman had died as the result of an illegal operation. Three medical men in succession attended her, and to one at least she confided the name of the abortionist. No information was given to the police so that the woman died without making a statement that could be given in evidence. The judge said that under such circumstances he had no doubt it was the duty of the medical man to communicate with the police so that steps might be taken to assist in the administration of justice. There were cases when the desire to preserve professional confidence must be subordinated to the duty of every good citizen to assist in the investigation of serious crime. It might be the moral duty of the medical man, even in cases where the patient is not dying or not unlikely to recover to communicate with the authorities when he sees good reason to believe that a criminal offence has been committed. This pronouncement led the Royal College of Physicians, London, in January, 1916, to pass a series of resolutions concerning cases of criminal abortion. In these they expressed the opinion that a moral obligation rests upon every medical practitioner to respect the confidence of his patient, and that without her consent he is not justified in disclosing information obtained in the course of his professional attendance on her. Also that every medical practitioner who is convinced that a criminal abortion has been practised on his patient should urge her, especially if she is likely to die, to make a statement which can be taken as evidence against the person who has performed the operation, provided her chances of recovery are not thereby prejudiced. If she refuses he is under no legal obligation (so the College was advised) to take further action. Before taking any steps which may lead to legal proceedings a medical practitioner will be wise to obtain the best medical and legal advice obtainable, "since in the present state of the law there is no certainty that he will be protected against subsequent litigation."

Before issuing this memorandum the British Medical Association had an interview with the Lord Chief Justice, the Attorney-General, and the Public Prosecutor, when the Public Prosecutor explained that the authorities desired that medical men should report abortions attempted or procured by third parties when the doctor was of opinion that the patient was likely to die. As appears from the resolutions, the College advised their members not to give effect to these wishes. The British Medical Association adopted the same attitude. This view, however, does not meet with universal medical approval. Dr. Sidney Smith says, in his work on Forensic Medicine, 1925: "It is no part of a doctor's duty to act as a detective, but it is equally certain that it is no part of his duty to act as a screen for the professional abortionist." Similar views are expressed in Dr. Robertson's "Medical Conduct and Practice" (1921). Since 1916, when the College of Physicians passed their resolutions, the practice of abortion has greatly increased. For instance, last week I noticed no fewer than five reported cases, in all of which I think the women had died. The question is whether, apart from legal obligation, the medical profession are justified in helping to conceal acts of this character. Of course a good deal depends upon the facts of the particular case. If the patient is not seriously ill, it would seem that the doctor is not justified in making a disclosure unless there are special circumstances. For instance, if the case is one of a series in which operations have been performed by the same abortionist. An East-end doctor, tried for murder, had kept records showing that he had performed no fewer than 400 abortions. Considering the prevalence of abortion the leaders of the profession are undertaking a serious responsibility in advising practitioners in such emphatic terms to disregard illegal acts of a most pernicious character.

To sum up, everyone recognises the necessity and importance of medical confidences. Everyone recognises that they are sacred and precious. But we must recognise also that the rules regarding them exist for the welfare of the community and not for the aggrandisement or convenience of a particular class. We must recognise, also, that they must be modified to meet the inevitable changes that occur in the necessities of various generations. As Cicero says: "*Salus populi suprema lex esto*," or in English, "Let the good of the people be the paramount law."

COLOUR TESTS FOR VITAMIN A.

THEIR APPLICATION TO NATURALLY OCCURRING PRODUCTS.

BY STANLEY G. WILLIMOTT, PH.D., B.SC.,
AND
FRANK WOKES, B.SC., F.I.C.

(*From the Biochemical Laboratory, Cambridge, and the University of Liverpool.*)

Rosenheim and Webster [1] have recently published in this journal a study of some of the colour tests suggested for vitamin A. This work, which was confined to oils derived from the animal kingdom, showed that there is an apparent relationship between the results of feeding experiments and the intensities of colour obtained with arsenic trichloride (Kahlenberg's reagent),[2] which has been chiefly used by Rosenheim and his co-workers. A number of other reagents, however, have been suggested for vitamin A by different investigators, including concentrated sulphuric acid (Drummond and Watson),[3] powdered phosphorus pentoxide (Fearon),[4] trichloracetic acid alone (Rosenheim and Drummond),[5] or with pyrogallol or other polyphenols (Fearon),[4] and antimony trichloride (Carr and Price).[6] Of these, it has recently been demonstrated simultaneously by Rosenheim and Webster, [7] [8] [1] and by Willimott, Moore, and Wokes,[9] [10] that Fearon's trichloracetic and pyrogallol reagent is not specific to vitamin A. So far as the remaining colour tests are concerned, their specificity is not yet clearly established, and it is obvious that many further data will be required, especially on foodstuffs of vegetable origin which have been shown by feeding experiments to contain vitamin A.

Relative Sensitiveness of Colour Tests.

At the outset* of our investigation of this problem it seemed advisable to ascertain the relative sensitiveness of the four colour tests under parallel conditions. For this purpose we employed a number of cod-liver oils, whose potency in vitamin A was known from feeding experiments, and for which the analytical constants had been obtained. A method was then required for the controlled quantitative destruction of the vitamin in a concentrated source, such as cod-liver oil. It was shown by Zilva,[11] in 1919, that exposure to ultra-violet rays destroys the vitamin A in butter. More recently Peacock [12] observed the same effect in cod-liver oil, using both sunlight and various other sources of the actinic rays, but in his paper in this journal no details were given of the period of exposure or of the distance from the mercury-vapour lamp. Holmes and Pigott [13] independently confirmed Peacock's conclusions in regard to the destructive action of the actinic rays in sunlight. Working in Prof. E. C. C.

* In this portion of the work a grant towards the expenses was received from the Pharmaceutical Society of Great Britain.

Baly's laboratory with a Hewittic quartz mercury-vapour lamp at a distance of 3 inches, we have been able to show that complete destruction of vitamin A in a potent oil occurred within two hours. The four colour tests were applied to samples withdrawn at frequent intervals during the course of the destruction, and it was found that concentrated sulphuric acid and phosphorus pentoxide became negative after an hour's exposure, and would therefore seem to be only about half as sensitive as the arsenic trichloride and antimony trichloride tests. Fearon's trichloracetic and pyrogallol test, on the other hand, persisted with undiminished intensity throughout five and a half hours' exposure, and was still quite definitely positive when the experiment was discontinued, thus confirming its non-specificity.

Disturbing Factors in the Application of Colour Tests.

Employing a Lovibond tintometer, as described by Carr and Price,[6] we succeeded in obtaining on these samples of oil withdrawn at five-minute intervals quantitative readings of the blue colour given by arsenic trichloride and by antimony trichloride. Since it has been suggested by Rosenheim and Drummond,[5] and by Takahashi and others,[14] that the blue colour is indicative of vitamin content, we used these readings to measure the amount of vitamin destroyed by the ultra-violet rays. Similar results were obtained with the two reagents, but antimony trichloride was found rather more sensitive, the blue colour persisting longer, and enabling us to take readings down to about 70 per cent. destruction, using the 30-second limit we have suggested.[10] A somewhat extended study of Carr and Price's method, to be published elsewhere,[35] has led us to the conclusion that it is necessary to pay attention to a number of factors, including temperature, time at which reading is taken, concentration of reagent, and of vitamin, if reliable results are to be obtained.

In the course of this work on irradiation of cod-liver oils an important observation was made that destruction of the vitamin continued after the oil had been removed from the action of the rays, even though it was protected from the action of daylight and tightly stoppered. Thus the actinic rays would seem to set in train destructive processes which apparently continue, month after month, until the whole of the vitamin is rendered inactive. An oil, for instance, in which only 3 per cent. of the vitamin A was destroyed at the time of irradiation, was found three months later to have lost 25 per cent.[15] Strong emphasis is therefore laid upon the necessity of protecting all cod-liver oil, and also other sources of vitamin A, such as milk and butter, from even a few minutes' exposure to the actinic rays. Otherwise, an oil whose original potency had been ascertained by laborious and costly animal experiments (cf. Willimott and Wokes, 1925)[16] might have lost subsequently a serious amount of its vitamin before being used clinically.

TABLE I.—*Pigments Involved in Photosynthesis.*

—	Suggested formula.	Colour by transmitted light.	M.P.C.
Chlorophyll A	$C_{55}H_{72}O_5N_4Mg$.	Bluish-green	Becomes viscous at 117–121°.
„ B	$C_{55}H_{70}O_6N_4Mg$.	Green	Becomes viscous at 120–130°.
Carotin ..	$C_{40}H_{56}$	Red	167·5–168°.
Xanthophyll	$C_{40}H_{56}O_2$	Yellow to orange	173–174° (Schertz).[19]

Another disturbing factor in the application of colour tests, especially to foodstuffs of vegetable origin, is the occurrence of various pigments. Even in cod-liver oil, Drummond and his co-workers,[17] in their recent comprehensive attempt to isolate vitamin A, found a close association between the vitamin and the lipochrome pigments of the oil. Takahashi and his colleagues[14] obtained a similar coloured concentrate, which they called "biosterin." These facts led Drummond to reconsider the theory originally put forward by Steenbock,[18] in 1919, of the possible identity of vitamin A with one of the lipochrome pigments. Of the many types of pigment found in plants, those most closely concerned with vitamin A are undoubtedly the group of four pigments involved in photosynthesis, the more important properties of which are summarised in Table I. from results published by Willstätter.

Relation of Vitamin A to Photosynthetic Pigments.

In some unpublished experiments, Willimott and Moore attempted to ascertain whether chlorophyll A or B could function as possible precursors of vitamin A. Our experience was that chlorophyll extracted from nettle leaves and other sources induced growth in rats on a vitamin A-free diet. Whether this was due to the chlorophyll itself or to the presence of traces of vitamin adsorbed upon it remains an open question, the latter explanation being the more feasible. A commercial sample of flake chlorophyll, supplied by a leading maker as supposedly pure, when fed to rats gave a definite negative result, but, unfortunately, was found to be contaminated with copper. It is noteworthy that phytol, a product of the hydrolysis of chlorophyll, was tested independently by Javillier[20] and his co-workers, and by Drummond,[17] in 1925, with negative results in both cases.

It is somewhat surprising that of the other two photosynthetic pigments carotin has received by far the most attention, although it occurs in the green leaf in smaller amount than does xanthophyll. Perhaps this is explained by the fact that vitamin A accompanies carotin rather than xanthophyll in the phase test. Carotin was fed by Drummond[21] in 1919, by Miss Stephenson[22] in 1920, and again by Drummond[17] in 1925, in every case with negative results. A most interesting colour reaction of carotin is its behaviour with either arsenic trichloride or antimony trichloride. In each case a deep *permanent* blue is obtained. In the application of colour tests for vitamin A to foodstuffs and pharmaceutical preparations these reactions are of peculiar significance.

In the case of xanthophyll, which also gives a permanent blue with these reagents, Drummond was unable to obtain a specimen sufficiently pure for feeding, while in 1920 Rosenheim and Drummond,[23] who fed an impure preparation of xanthophyll to rats, obtained a growth response, but rightly considered the results inconclusive. In view of this, it was thought worth while to prepare pure crystalline xanthophyll and to feed it to vitamin A-deficient rats. This experiment of Willimott and Moore[24] showed conclusively that xanthophyll is not identical with vitamin A, a result which had been indirectly obtained by Palmer and Kempster,[25] who fed chicks for two generations on a diet devoid of xanthophyll and still obtained normal growth and well-being, although the eggs and tissues were practically free from pigment.

It would thus appear probable that vitamin A is not identical with any of these four photosynthetic pigments. Steenbock's theory has indeed been abandoned by its originator,[26] and by Drummond,[27] and other workers. Nevertheless, these pigments, which are found widely scattered throughout the vegetable kingdom, as well as in certain animal products, cannot be ignored when colour tests are being applied to foodstuffs, because both carotin and xanthophyll give *permanent* blue colours with arsenic trichloride and antimony trichloride and therefore interfere with the *transient* blue colours given by these reagents with vitamin A. The question arises: Is it possible to remove carotin and xanthophyll, and chlorophyll also if present, from foodstuffs and natural products without affecting the content of vitamin A?

The method which appeared to us to offer most promise was adsorption of the pigment by means of a suitable agent. A series of finely powdered charcoals and other adsorbents was obtained and their relative adsorptive capacities determined. The

results obtained, details of which will be published elsewhere, showed that it is possible to remove any of these interfering pigments from foodstuffs, such as butter-fat, egg yolk fat, maize oil, spinach, &c., by several hours shaking of a petroleum ether solution with a good charcoal, using approximately 10 g. to each 100 g. of butter-fat, &c. The vegetable charcoal norit gave the best results. Whether in the removal of the pigment the vitamin A also is affected is a point we have had under consideration. Evidence so far obtained, both by feeding experiments and by colour tests, would seem to indicate that vitamin A is not adsorbed to any very considerable extent by charcoal used to remove carotin and xanthophyll. In the meantime, employing this technique for the removal of interfering pigments, we have applied the above described colour tests to a variety of foodstuffs and natural products whose potency in vitamin A has been ascertained by feeding experiments in most cases. In Table II. are summarised the results obtained with cod-liver oils, their unsaponifiable fractions, and other derivatives.

Colour Tests for Vitamin A in Cod-liver Oils and Derived Products.

The three samples of cod-liver oil obtained from different sources† gave practically identical results with arsenic trichloride and with antimony trichloride; the colour persisted with undiminished intensity when equivalent amounts of the respective unsaponifiable fractions were tested. The Iceland oil, which gave the most intense reactions, has been found to protect completely from vitamin A-deficiency albino rats to which it was given as sole source of this vitamin over a period of several months, in doses of 20 mg. When the vitamin A in these oils is destroyed in various ways, by treatment with concentrated sulphuric acid, or with phosphorus pentoxide, by irradiation, or by aeration at different temperatures, we have always found all the tests agree in becoming negative. The results we obtained by aeration, which are given in detail elsewhere,[28] show close agreement with those obtained in 1925 by Rosenheim and Drummond,[5] who found that the arsenic trichloride test became negative after 1 hour's aeration at 100° C.

Since cod-liver oil is known to contain two of the three different fat-soluble vitamins, it seemed desirable to ascertain whether the presence of vitamin D in any way interfered with the colour tests for vitamin A. For this purpose the Glaxo Research Laboratories kindly supplied us with a sample of cod-liver oil from which vitamin D had been completely removed by the Zucker [29] process. Feeding experiments had shown this to be a D-free source of vitamin A, and on applying the colour tests strong positive reactions were obtained in each case. On the other hand, a concentrate of vitamin D (ostelin) obtained from the same laboratory gave negative results. These findings indicate that the colour tests for vitamin A are not qualitatively interfered with by the presence of vitamin D, an observation of interest in view of the fact that the actinic rays necessary for the production of vitamin D are now known to have a destructive action on vitamin A.

Olive oil and oleic acid appear to exert some inhibitory effect upon the application of the colour tests. Pure olive oil and oleic acid of themselves give negative results, and would thus appear to be possible diluents for cod-liver oil. Olive oil has in fact been frequently used in this capacity, but its unsatisfactoriness is obvious, because of the possible presence of organic peroxides, which gradually destroy the vitamin A. Another disadvantage where feeding tests are being made in parallel with colour tests is the fact that low concentrations of cod-liver oil (5 per cent.) in olive oil may not be detectable by the colour tests, even when freshly prepared solutions are examined.

† We are indebted to Messrs. Allen and Hanburys, Parke, Davis and Co., Southall Bros. and Barclay, and Evans, Sons, Lescher and Webb for supplying samples of cod-liver oil of definite origin, also much information in regard to the various processes adopted in their preparation.

In the case of cod-liver oil, we have not been able to remove the natural pigments by adsorption on to charcoal, but the amount present in the pale refined oils usually supplied for medicinal purposes is not sufficient to cause appreciable interference with the colour tests. It is significant that carotin or xanthophyll‡ (1 in 2000) added to a cod-liver oil, whose vitamin A has been completely destroyed by irradiation, causes positive results to be given by arsenic trichloride or antimony trichloride. Fortunately, it is possible to remove these pigments by shaking with a suitable charcoal; also other experiments show that this procedure does not appear to remove any vitamin present.

Colour Tests for Vitamin A in Foodstuffs and Natural Products.

On turning to foodstuffs and natural products (Table III.) containing vitamin A, it is impossible to obtain satisfactory results until the interfering pigments have been removed by adsorption. Butter-fat, after complete decolorisation, still gave definitely positive tests. An interesting discovery was that annatto, which is commonly used to colour butter, butter substitutes, and cheese, gives a transient blue colour with the vitamin reagents, due probably to the constituent bixin. Fortunately, this also could be removed by adsorption. In order to ascertain the possibility of applying the colour tests to infants' foods, samples of dried milk prepared by the roller and by the spray process were also tested. Three samples of lard examined all gave negative results.

The samples of orange and of lemon rind oils had been prepared for us by Mr. C. P. Wilson in the research laboratory of the California Fruit Growers Exchange at San Dimas by cold expression from the peel of fresh ripe fruit. They had been carefully protected from the action of light and air. The orange oil was of deep red-brown colour, and it was impossible to observe the characteristic blue colour until the pigment had been removed. The lemon oil was of a yellow colour, and also required to be decolorised. The results obtained with colour tests on these rind oils, after decolorisation, agreed with the findings of Morgan [30] and ourselves [31] working on the actual rinds, and testing for vitamin A by feeding experiments. Our results go to confirm Morgan's conclusion that fresh orange rind oil is one of the most potent sources of vitamin A in the vegetable kingdom. In the case of the orange juice, which was obtained from fresh ripe Californian navel oranges (Sunkist variety) 125 c.cm. of juice was concentrated in vacuo, the residue taken up in a little water, well extracted with chloroform, decolorised, and evaporated nearly to dryness. The product gave definitely positive reactions with the two colour tests, arsenic trichloride and antimony trichloride, but doubtful results with the other two tests. The same juice tested on albinos for vitamin A had a curative dose of 5 c.cm. per head per day.[34]

Another potent source of vitamin A in the vegetable kingdom is spinach leaves. An acetone-ether extract of early spring spinach was prepared of such potency that 25 mg. was a protective dose for rats on an A-free diet. This extract was taken up in petroleum ether and decolorised with norit, and the colourless filtrate was concentrated in vacuo and tested. Since Chick and Roscoe [32] found fresh spinach leaves to be a source of vitamin A practically free from vitamin D, the procedure has been adopted in many laboratories of using fresh spinach leaves as a source of vitamin A when testing for vitamin D. In view, however, of the large dose of the fresh leaf that may be required (Chick and Roscoe found that over 2 g. may be necessary) and the wide variations which may occur in vitamin content, we [33] suggested some time ago that an acetone-ether extract of carefully dried spinach leaves might prove a much more stable and concentrated source of vitamin A. It is of interest to

‡ Crystalline samples of pure carotin and xanthophyll were kindly supplied by Prof. Heilbron, of Liverpool University, for the purpose of this work.

NOTES ON TABLES II. AND III.

(*a*) All these tests were carried out in dry test-tubes, using anhydrous solvents.

(*b*) Blanks in this column signify that data are not available.

(*c*) Doubtful result, probably negative.

(*d*) Colours greenish-blue, and fade rapidly.

(*e*) Dilution refers to volume in volume.

(*f*) Pure specimen kindly supplied by Prof. Heilbron.

(*g*) Petrol ether extract of clarified fat, filtered, shaken with norit, then refiltered, giving water-white solution.

(*h*) A purely vegetable product of firm consistence made from nut oils. Some samples of margarine contain a proportion of butter, in which vitamin A can be detected by colour tests.

(*i*) An aqueous alcoholic extract of the fruit of *Bixa orellana*.

(*j*) Vitamin A content of different samples of beef suet was found to be variable.

(*k*) Unsaponifiable residue from ethereal extract, taken up in petrol ether, depigmented with norit, filtered, and evaporated at 38° to 40° C.

note that we have since found such an extract to be a highly potent source of vitamin A, when measured by either animal experiments or colour tests, and further experiments have also shown that it contains no appreciable amount of vitamin D. Finally, a number of vitamin A-containing foods, such as carrots and yellow maize, were dried at 40° C. and extracted with ether, the ether-soluble matter being then decolorised and examined as above described.

It will thus be seen that the successful application of colour tests for vitamin A to pharmaceutical materials and to foodstuffs demands the careful observation of a number of precautions, some of which are only just beginning to be understood. In view of the laborious and costly nature of feeding experiments, and the wide margin of error in the results, it is obvious that any chemical means which give promise of really estimating the vitamin should be tried on as wide a range of natural products as possible. When the specificity of such tests has been definitely established, and a quantitative technique worked out, the way may be open to a new field of investigation of the first importance in human nutrition and well-being.

STREPTOCOCCAL SEPTICÆMIA

TWO CASES TREATED WITH CONCENTRATED STREPTOCOCCAL ANTITOXIC SERUM.

BY W. SANDERSON, M.B., CH.B. EDIN.,
HON. LARYNGOLOGIST AND AURIST, ROYAL SOUTHERN HOSPITAL, LIVERPOOL;

NORMAN B. CAPON, M.D. LIVERP., M.R.C.P. LOND.,
HON. PHYSICIAN, ROYAL SOUTHERN HOSPITAL, LIVERPOOL;
AND
HENRY H. MACWILLIAM, M.B. R.U.I., D.P.H.,
MEDICAL OFFICER, WALTON INFIRMARY, LIVERPOOL.

THE gravity of streptococcal septicæmia scarcely needs to be emphasised. In a recent series of 60 cases at the St. Louis Children's Hospital[1] the infection was due in 51 cases to hæmolytic streptococci and in nine to non-hæmolytic streptococci; only one of the hæmolytic cases recovered. The details of Case 1 are published in the hope that the treatment adopted at a time when the patient appeared to be beyond hope of recovery may be found to give equally good results in other cases of streptococcal septicæmia.

CASE 1. *Septicæmia Secondary to Otitis Media in a Child* by Drs. Sanderson and Capon).—The patient, aged 6¼ years, was an only daughter. She was born in Singapore, but had been in England for about ten months. Her only previous illness was broncho-pneumonia when 1 year of age. On March 14th, 1927, while at school, she came under the care of Dr. R. M. Littler, of Southport, on account of slight pyrexia, followed in three days by left-sided otorrhœa. Careful inquiry elicited that she had been troubled with a slight cough since Christmas, 1926, and that she had seemed lethargic and drowsy for about three weeks before the ear began to discharge. It is noteworthy that there had been no previous aural trouble, and that little pain was present. The throat was normal.

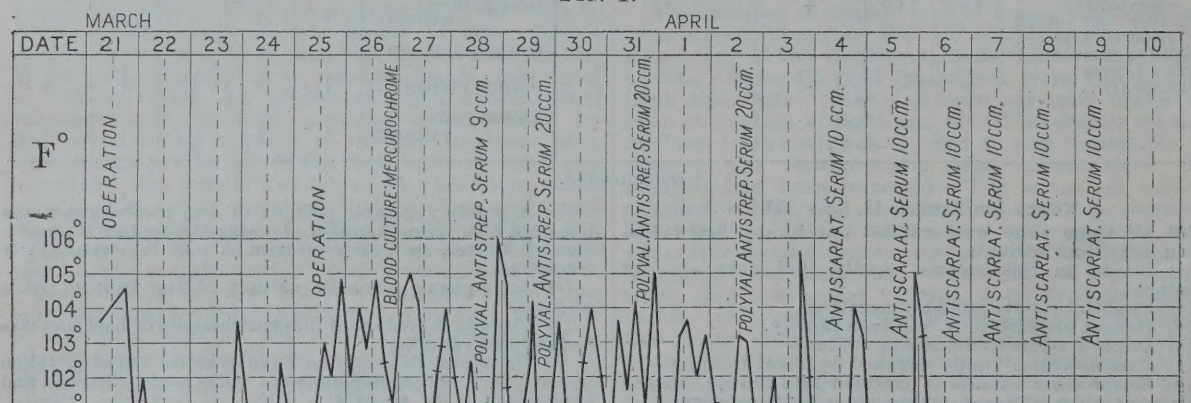
On March 21st she was seen in consultation by one of us (W. S.), who found the left tympanic membrane to be red and bulging, with sagging of the postero-superior wall of the meatus. There was no tenderness behind the ear. The mastoid antrum was opened on the same day and many air cells were found to contain pus. The temperature fell to normal, but began to rise again (see Fig. 1).

On the 25th the temperature was still ascending; the lateral sinus, middle cranial fossa, and cerebellum were exposed and examined; no local cause of pyrexia was found. On March 26th the patient was seen also by N. B. C. She then looked extremely ill. The tongue was coated, the breath foul-smelling, the lips were dry and there was a slight follicular infection of the tonsils. The chest showed no abnormal signs except those of slight bronchitis. The spleen was not palpable. The pulse was rapid (150) and soft. In the heart the only abnormal sign was a soft blowing systolic bruit at the pulmonary area. The eye-grounds were normal. The urine (not a catheter specimen) was slightly turbid and contained a trace of protein, much acetone, and microscopically only a few epithelial cells. No reducing substance was found.

With the evening rise of temperature the patient's condition deteriorated still further and a blood culture was taken at midnight on the 26th. Four broth tubes were inoculated with varying quantities of the patient's blood, and at the same time 3 c.cm. of a 1 per cent. mercurochrome solution were injected intravenously. On cultivation of the blood-broth each of the four tubes was found to contain a pure growth of hæmolytic streptococci. Daily subcutaneous injections of polyvalent antistreptococcal serum were then instituted; the first dose was 9 c.cm. and subsequent doses were 20 c.cm. Two well-known brands of serum were used without any appreciable effect. The patient's general condition became extremely bad; slight rigors developed and the peculiar smell of the moribund septicæmic patient was noted. Granular casts appeared in the urine.

It was then decided to employ concentrated scarlatinal streptococcal antitoxic serum (Burroughs Wellcome and Co.) and the special advice of Dr. G. R. James, who has worked for a considerable time in Prof. J. M. Beattie's laboratory upon streptococci, was invited. He recommended intramuscular administration of the serum in 10 c.cm. doses; the effect will be noted in Fig. 1. The patient's clinical condition improved pari passu with the cessation of pyrexia and the rapid improvement which resulted seems almost certainly to have been due to the antitoxic power of the serum used. The wound has not presented any unusual features and is now healed. The patient has been free from fever since April 9th. She is rapidly losing the anæmia and marasmus which were previously so marked, and her condition may be described as excellent. She is now walking again, and full recovery may be anticipated.

FIG. 1.



Temperature chart in a case of septicæmia treated with streptococcal antitoxic serum.

The wound has not presented any unusual features and is now healed. The patient has been free from fever since April 9th. She is rapidly losing the anæmia and marasmus which were previously so marked, and her condition may be described as excellent. She is now walking again, and full recovery may be anticipated.

CASE 2. *Puerperal Septicæmia* (by Dr. MacWilliam).—Mrs. E. E., aged 34, had her seventh confinement on Jan. 12th, 1927. She was attended by a midwife and the child was born without any difficulty. On the third day she had a rigor, and on the 25th she was sent into Walton Infirmary.

On *admission* the temperature was 102·2°, pulse 112. There were no local signs and a blood culture was negative. Collosol iodine, 100 c.cm., was given intravenously, and parathyroid gr. 1/10, and Kalzana (two tablets thrice daily), were ordered. On the 27th temperature was normal and she seemed much better; but on Feb. 2nd a swelling was discovered in the left labium and the temperature began to

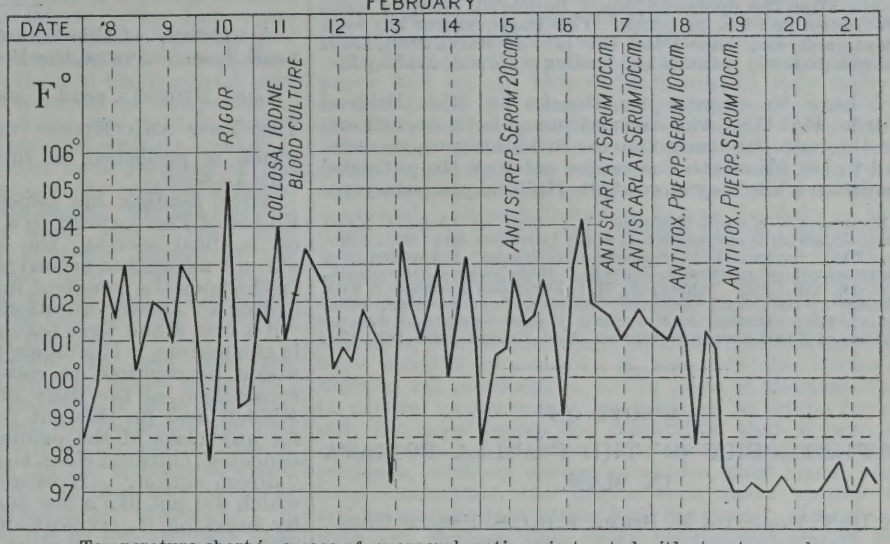
[1] Abt's Pediatrics, 1925, vi., 530.

rise. On the 5th an incision was made in the swelling under nitrous oxide anæsthesia, but the contents proved to be mainly blood-clot. On the 6th the temperature rose to 102·6°. The patient became steadily worse, and on the 10th she had a rigor (see Fig. 2). On the next day she looked very ill; the spleen was palpable and on culture hæmolytic streptococci were found in the blood. Although she was so ill the patient herself said she "felt lovely."

On the 15th I gave 20 c.cm. of ordinary antistreptococcal serum subcutaneously with the intention of giving larger doses intravenously later; but on the evening of the 16th Dr. G. R. James kindly provided me with some concentrated scarlatinal streptococcal antitoxic serum (Burroughs Wellcome and Co.) and soon after midnight on the 17th 10 c.cm. of this serum were given intramuscularly. At midday the patient was considerably better and the dose was repeated. On the 18th and 19th I gave two 10 c.cm. doses of concentrated streptococcal antitoxic serum prepared by the same firm from a puerperal streptococcus. The only reason for using a different type of concentrated streptococcal antitoxic serum was that a further supply of the scarlatinal variety was not immediately available.

On the 20th pulse and temperature were normal, the spleen was only just palpable and the general condition was excellent. There were no further rises of temperature and the patient was discharged cured on March 9th.

FIG. 2.



Temperature chart in a case of puerperal septicæmia treated with streptococcal antitoxic serum.

The prognosis in this case seemed very bad. If recovery was the result of treatment it is remarkable.

Clinical and Laboratory Notes.

INFECTION OF THE NASAL SINUSES IN RELATION TO INSANITY.

BY J. GAY FRENCH, M.S. LOND., F.R.C.S. ENG.,
SURGEON-IN-CHARGE EAR, NOSE, AND THROAT DEPARTMENT, ROYAL FREE HOSPITAL.

CONSIDERABLE attention has been paid of late to the relation of septic foci to insanity. This attention, however, has been directed to sepsis of teeth and tonsils to the relative exclusion of the nasal sinuses, and for this reason the following two cases are recorded. It has proved possible to find references (given at the end of this article) to 19 cases only of the same kind, in 11 of which the patients were males, and in seven females, the sex of one not being mentioned. The distribution of sepsis in the sinuses may be summarised as follows:—

Maxillary antrum	U. .. 8 cases	Ethmoids	U. .. 9 cases
	B. .. 2 ,,		B. .. 4 ,,
Frontal sinus	U. .. 4 ,,	Sphenoidal sinus	U. .. 3 ,,
	B. .. 3 ,,		B. .. 2 ,,

U. = Unilateral. B. = Bilateral.

In many of the cases more than one sinus was involved, and in all recovery is reported as following drainage. The two cases now to be reported are as follows:—

CASE 1.—Mrs. A., aged 59, was married at the age of 31, and had one daughter. She was admitted to Holloway Sanatorium on July 17th, 1924, with two months' history of depression and apathy. She said she had "committed the unpardonable sin of blasphemy," and that she had heard the Devil's voice tempting her to kill herself (she had twice attempted suicide and had asked her nurse to kill her). Twenty-five years previously she had been treated in a nursing home for depression.

On admission she was much depressed, and physically was frail, kyphotic, and pigeon-breasted, with a sallow, dry skin. On treatment with thyroid extract increasing from gr. ¼ to gr. 1 three times a day she improved considerably, and in August, 1924, was allowed home; but in a fortnight she was readmitted with delusions of unworthiness and wrongdoing, threatening to take her life. Thyroid treatment was resumed and in October she had improved on grs. 2 t.d.s. By December, 1924, she was more cheerful, but still thought "that God was punishing her."

I saw her in December, 1924, because of persistent nasal and post-nasal discharge which she had noticed for some years. On examination both nasal fossæ contained pus; the ethmoids were swollen and septic. Transillumination showed both antra and frontal sinuses dark. On puncture of the antra both contained pus; X rays showed all nasal cavities to be involved. Operation was advised and the patient was transferred to a nursing home where, under a general anæsthetic on Jan. 20th, 1925, all the cavities, including both sphenoidal sinuses, were opened by the intranasal route, and all showed gross sepsis, a quantity of necrosed bone being removed from both ethmoidal regions. Subsequent treatment consisted in a daily washing-out of all cavities with 1 drachm of a 10 per cent. solution of protargol in a pint of normal saline.

She returned home on Feb. 11th, physically well, but depressed. By April, 1925, she was much better, took up her household duties, and said that "the mists had cleared away." There was still a considerable nasal discharge, for which a daily lavage was carried out by herself at home. I last saw her on March 23rd, 1927, when the nasal discharge had practically ceased and she was mentally perfectly normal.

CASE 2.—Mrs. B., aged 55, was admitted to the Holloway Sanatorium on Jan. 9th, 1926, with a two months' history of restlessness, depression, and marked insomnia, accompanied at times by confusion. There were no hallucinations, nor definite delusions. The complexion was muddy, and the patient stated that she had for some time noticed an offensive discharge from the left nostril. While under treatment the patient complained daily of headaches and, in March, 1926, tenderness was noticed over the left frontal sinus and the left maxillary antrum.

I saw her in April, 1926, and found pus on the left side of the nose; the left frontal sinus and antrum were quite dark on transillumination, and the left antrum on being punctured was full of pus. X ray showed that the left frontal sinus, left antrum, and left sphenoidal sinus were infected, and I advised operation. She was transferred to a London nursing home, but immediately became restive, agitated, and maniacal; she was given gr. 1/100 of hyoscine hydrobromide hypodermically, and returned to the sanatorium on the same day.

The operation of intranasal drainage of the left frontal, maxillary, and sphenoidal sinuses was ultimately performed at the sanatorium on May 8th, 1926. After the operation the cavities were douched out daily with the protargol solution. By May 25th the colour was much improved and there was no headache, but the patient was still agitated, She was discharged from the sanatorium on June 5th, one month after the operation, much improved, showing more self-control and less agitation. This improvement has been maintained, and when I last saw her, on March 28th, 1927, she was perfectly rational and leading a normal, healthy life.

I have to express my thanks to Miss Mildred Warde, F.R.C.S., who assisted me at both operations, for the help she has given me in looking up records, and to Dr. Elizabeth Casson for notes on the patients' condition while they were at the Holloway Sanatorium.

A NOTE ON
HYPERTROPHY OF THE PAPILLA FOLIATA IN MAN.

BY B. T. ROSE, CH.M. BIRM., F.R.C.S. ENG. & EDIN.,
ASSISTANT SURGEON, GENERAL HOSPITAL, BIRMINGHAM.

DURING the last four years my attention has been frequently drawn to a condition of the tongue which receives no mention in any of the text-books of surgery that I have been able to consult. The condition appears to be a mild inflammation and hypertrophy of the rudimentary papilla foliata met with on either side of the tongue in man.

In all, 19 cases have been observed in the last four years, all of them males, with an age variation from 20 to 60 years. The patient states that he is experiencing a pricking sensation in the side of the tongue and is often in dire distress, believing that he is developing cancer. No definite ætiological factor can be traced except the sex incidence. Dental sepsis is not a factor, since it occurs both in clean and dirty mouths; further, the site of the trouble is too far back to be influenced by dental trauma. Occupation, diet, and smoking appear to exert no causative effect, and syphilis has been absent in the majority of the cases. Many of the patients appear to be of rather a sensitive and nervous type.

The condition is probably inflammatory in nature but is not associated with acute or chronic superficial glossitis, the rest of the tongue mucosa appearing quite healthy. It may be unilateral or bilateral, and in varying degree on each side. Examination of a portion of tissue excised from a severe case showed some hypertrophy of the papilla, with a mild degree of chronic inflammatory change. The patient complains of a pricking or burning sensation in the affected area of the tongue which is not increased by irritant foods or drink, but occurs especially at night. Examination shows that the papillæ on one or both sides are raised, reddened, and granular in appearance. There is no ulceration, and the rest of the mucosa of the tongue, including the circumvallate papillæ, is healthy. There is no induration and but little tenderness on pressure, no lymph gland enlargement occurs, and the general health is not affected.

Treatment begins with a complete dental toilet, and in most cases the condition will subside with the use of alkaline mouth washes and the local application of 5 per cent. chromic acid solution. Some cases are very resistant, however, and a variety of local applications may be tried, the most generally useful being salicylic acid. As a last resort destruction of the area with the actual cautery will always result in cure.

Medical Societies.

MEDICO-LEGAL SOCIETY.

A MEETING of this Society was held on June 23rd, Lord Justice ATKIN, the President, being in the chair.

Lord RIDDELL read a paper entitled

THE LAW AND ETHICS OF MODERN CONFIDENCES,

which is published in full on p. 4 of this issue of THE LANCET.

After reading his paper, Lord Riddell said the Editor of THE LANCET in a recent book had a chapter on medical secrecy, the views set forth in which did not altogether accord with those held by himself. In the book the comment made on the obligation of the doctor to answer questions in the witness-box was "if a firm stand were taken by the medical profession in the matter, it is unlikely that any prolonged conflict would be required to establish in the law courts a recognition of the duty of medical secrecy." Lord Riddell said he thought it a most dangerous thing for any class of the community, particularly for an educated, cultured class, to engage in what was termed "direct action." If every class of the community which did not like a law endeavoured to get it altered by breaking it, civilisation was bound to break up. There were proper ways of trying to get laws altered. He admitted that other less lawful means had been adopted, and sometimes successfully, but the whole basis of civilisation consisted of the recognition of certain conventions.

Discussion.

Sir WILLIAM COLLINS reminded members that in his first inaugural address he claimed that this Society would act very usefully in discussing subjects in which the lawyer, the doctor, and the layman were deeply interested, and he did not know one to which that applied more aptly than that now being debated. The speaker agreed that the Hippocratic Oath, which some held to have solved the problem, was useless for the purpose; it meant that those who took it undertook not to divulge what they ought not to divulge. Lord Riddell had propounded nine conundrums, but he did not vouchsafe replies; it was noteworthy that he had taken a different position from that he took when, five years ago, he fell foul of Lord Dawson on the sacredness of medical confidence. Now he was prepared to concede that medical confidences should be sacred, but thought there were exceptions. Sometimes it might be the duty of the medical man not to divulge to the patient what the latter was suffering from; for example, in cancer it might be a detriment to the patient's welfare. But if the disease were syphilis, for instance, it was overwhelmingly the doctor's duty to tell the patient because of his danger to the community and the need of receiving prompt and thorough treatment. Sometimes it was not the doctor's duty to disclose, sometimes it was his duty not to disclose what had been imparted to him in confidential relationship. The difficult problems were those cases of abortion which were not likely to be followed by greater consequences. With regard to information obtained in a venereal clinic, Sir William Collins referred to the case of a Chester practitioner who refused in court to communicate information he had received in the clinic, justifying the refusal by the wording of the statutory regulations promising secrecy to the patient. The speaker considered that the medical man was justified in his attitude, and regretted that he did not go further and run the risk of contempt of court rather than divulge the secret. He imagined that there sometimes arose positions in which the medical man and the priest were placed in an identical position, and in which the secrets imparted would not be revealed, even to a judge in the high court.

Dr. F. J. McCANN said he did not think there was any department of practice in which questions of medical confidence arose more frequently than in that of obstetrics and gynæcology. In venereal disease the difficulties were very great. He gave two examples. The first was that of a young married woman, mother of two children. She had acute syphilis, so acute that her condition had been diagnosed as influenza. He told her the nature of her illness; she confessed to adultery. He told the husband only that she had syphilis, that it would be dangerous to have intercourse with her, and that the children should not kiss her or use the same utensils without cleansing. He felt bound thus to protect each member of the family. In the second example the wife of a friend had a verified gonorrhœal discharge. He did not tell her its nature. She went away and a year later returned and asked what was the nature of the discharge for which she had been treated; asked why she wanted to know, she replied that she intended to divorce her husband. He felt justified in telling her the truth and a divorce followed.

On the subject of abortion, he held that the medical man should be a doctor, not a detective; but in regard to criminal abortion, if that was suspected, his method was to ask the patient if she had had abortion procured, and if so he assured her it would be for her good to tell him the manner in which it was brought about. He had in that way obtained information which was valuable for treatment; if the patient seemed likely to die he felt strongly that the doctor should inform the authorities. With regard to unmarried pregnancies, frequently a mistress called in a doctor to examine her servant and guaranteed his fee; was that acceptance or guarantee a justification to impart the diagnosis to the mistress? In such cases when the girl was pregnant he told her so and asked whether he should tell her mistress. If she objected he did not tell; if she consented he told the mistress. He thought the law might well be amended as regards cases in which the doctor discovers on examination absence of internal genital organs in the female. Having made such a discovery should he disclose it? And if he did so could a nullity suit be brought and a decree of nullity obtained? If a woman had had complete hysterectomy performed and kept that knowledge from the husband, should the doctor tell when he discovered it? And could such husband get relief? Female impotence he considered was far more common than male impotence, and all degrees of malformations were met within those organs.

Dr. GRAHAM GRANT contended that the moment a medical man entered the witness-box and had been sworn he was in the same position as any other witness. If in doubt whether he should or should not answer a particular question, he should seek the judge's ruling; that would transfer the responsibility to the judge.

Mr. ERNEST CLARKE contended that if the sanctity of professional confidence was removed, or whittled down, patients would become anxious and would not impart that information which was necessary to the doctor for adequate treatment. Rather than violate the secrecy of what had been told him, the doctor should be prepared to suffer imprisonment.

Dr. HALLIDAY SUTHERLAND said the doctor had no real privilege in these matters, for in recent cases of the kind, as soon as the judge told the doctor he must speak, he did so. The medical profession was not very well represented in Parliament. Lord Riddell must know that no reform had been carried except by direct action. The theme of the present paper was based on the hard case, and it was a dictum of the legal profession that "the hard case makes bad law." Patients went to the venereal disease clinics only because they had confidence in the promise of secrecy, and if they learned of cases in which this had not been respected they certainly would not continue to go to them. He had once been asked to see a man who was supposed to be dying of consumption, but the speaker formed the conclusion that his journey downhill was being assisted by the administration of arsenic. He therefore saw the wife alone and asked her who cooked her husband's food. She at once changed colour and demanded to know the reason of the question. He retorted that he did not think his food agreed with him. Matters improved, and he believed that he had in this case found a way out of a very difficult situation.

Sir WILLIAM WILLCOX thought that Lord Riddell's paper had set out this difficult subject very fairly; he had taken the stand that professional confidence should, wherever possible, be respected. But there were cases in regard to which the following of this strict line would be harmful to the community—i.e., where crime was being continued and was being concealed. In such instances it was the duty of the doctor to take action. At a certain hospital in London a number of cases of obvious instrumental abortion were admitted, and it was known that a particular abortionist was concerned in them. Several deaths resulted in the series. Ought the doctor to hold his tongue in such a case, when patients in that condition were steadily arriving? It was not the doctor's duty to act as detective, nor in cases of abortion due to natural causes was it his function to try to ferret out, by questioning, the possibility that it was a case of criminal abortion. But when there was clear evidence, without asking questions, that crime had been committed, the doctor took upon himself a serious responsibility if he held his peace. He agreed with Dr. McCann that every inducement should be used to get the patient herself to make a clean breast of the matter. If that was not acquiesced in, then, in certain cases, it was the duty of the doctor to inform the authorities, though he would be wise if, before doing so, he took the best available legal advice. Where a medical witness demurred to answering a question and the judge ordered him to answer, Sir William Willcox agreed that he should obey, but under protest. With regard to cases of suspected poisoning, the safe course was to have the excretions examined for poison. If poison was found, of course the authorities should be informed. Dr. Sutherland's wise action protected his patient and also stopped the nefarious practice.

Dr. MORGAN FINUCANE did not think that Lord Riddell had succeeded in showing that the law had much bearing on ethics and medical confidence. No doctor was justified in constituting himself a martyr by refusing to give evidence in court when ordered to do so. Venereal diseases would probably be notifiable before long, and then where would medical confidence stand? The medical profession must endeavour to march with the times and realise the trend of modern legislation.

Summing Up.

The PRESIDENT summed up the discussion. Lord Riddell had presented the subject in a clear and elaborate paper, for which the Society was greatly indebted. When, five years ago, Lord Dawson had introduced a similar subject, the President had stated his views, and he had seen no reason since to alter them. The position seemed to him to be as follows: One question was, What may a doctor tell, in law? That turned upon the question whether or not he was under a legal obligation not to disclose the information he obtained from the patient. He had no doubt that, subject to certain qualifications, it was an implied term of the contract of employment as a medical man that that medical man would not disclose, to the disadvantage of the patient, the information he obtained. The further question arose as to what were the limits of that obligation at law—i.e., not to disclose the information obtained? First, the doctor was not under an obligation to withhold information given to him which would enable a crime to be committed, and the speaker thought he was under no obligation to withhold information obtained from the patient that a crime was about to be committed. The President was not now dealing with the doctor's duty to volunteer that

information, but only with the point as to whether it was a breach of the contract if he did disclose it. It was plain that, in law, he was obliged to disclose the information he obtained from the patient if he was called upon as a witness in a court. There might be two opinions as to whether that ought to be the law, but there could not be two opinions as to whether that was the law at present. There might be involved large questions of social duty, as Lord Riddell had pointed out, all of them admittedly difficult questions; and circumstances might arise in which either the contract did not extend to withholding information in such circumstances because the contractual duty would conflict with the urgent and strong social duty; or that, though the doctor might be under a contract to his patient, yet it might be his duty, as a citizen and a man of honour, to break his contract, for there might be occasions on which a breach of contract was, ethically, justifiable. While a doctor might expose himself, technically, to an action for breach of contract, yet a court, in dealing with the matter, would always have to deal with the question of damages, and in such a case as he was predicating it was difficult to conceive that any jury or any judge would be likely to impose the burden of substantial damages upon him. But other difficult matters, apart from the contractual aspect, might arise. As a rule, the contract was made with the person who employed the doctor, and the person from whom the doctor received his remuneration was not in all cases the patient, such as where the doctor was asked by an employer to examine and treat his servant. And a very obvious case would be that in which a doctor was employed by an insurance company to report on the condition of a proposed assuree. It was plain that in such a case the doctor's contract was with the insurance company, and he could disclose to the latter the information he derived from the examination. He imagined that most doctors would consider themselves under a professional obligation not to disclose unnecessarily the information obtained from the examinee, who, however, was not a contracting party. That obligation it was very important to maintain. Whether the obligation rested upon contract, or upon something short of a legal obligation, an honourable professional understanding, the President held that there was immense importance in the point of view put forward by Mr. Clarke; it was of public importance that persons should be able to have recourse to doctors in full confidence so that they might fully disclose to them their disease and their history, without any anxiety that such would be made public. In regard to no class of case was it of more importance than concerning venereal disease. He could not understand how it would ever be possible to ensure satisfactory treatment of venereal disease, and to ensure that people so suffering would come for treatment in its early stages, or as soon as they could, unless there could be an absolute guarantee against publicity. It was of extreme moment that this confidence should be maintained. When dealing with the legal obligation to tell, he felt there were a great many cases in which the judge should exercise discretion—and it was often so exercised—as to whether he would enforce disclosure or not. There were instances in which the judge could tactfully say he did not think it would be to the public disadvantage if the information were not disclosed.

Then there arose the question as to when a doctor should tell. The cases put by Dr. McCann in illustration of the difficulties met with were distinguishable from each other. The first case raised the question as to disclosure to a third person of a confidence reposed by the patient—i.e., where a wife was suffering from syphilis—and the question for decision was whether the information should be imparted to the husband. He could hardly imagine a doctor in such circumstances as were related failing to take steps in some way to protect the young innocent husband and children. No doubt the obvious course was to insist on getting the permission of the patient to inform the husband, as Dr. McCann did. But each doctor must be the arbiter as to his own honour in particular circumstances. The other question Dr. McCann raised seemed to be a simpler one—namely, that in which the patient was suffering from a venereal disease—and the question was whether she herself should be told the nature of the disease. That did not involve a breach of professional confidence, and the President saw no difficulty in dealing with the position. He had often wondered why a doctor should so often feel it was within his discretion to refuse to tell a patient what he was suffering from. His own feeling was that if he asked a medical man what he was suffering from he was entitled to know, and if the doctor refused to give the information, he was taking upon himself a serious responsibility, even though it might be argued that the refusal was in the patient's interests. Dr. Sutherland had asked what the doctor should do when he found or suspected that a patient was being poisoned; the President did not think that this touched the matter under discussion. In those circumstances the duty of the doctor was to his patient. If he had information that the patient was being poisoned, why should he have qualms as to what information he should publish? What objection could there be to his protecting his own patient? It was not likely that the patient who was being poisoned would object to steps being taken in communicating the facts to the proper quarter. As to the kind of case spoken of by Dr. McCann where the doctor found the genital organs of a wife to be absent, that was a case for the doctor's discretion; the judge was not so well qualified to form an opinion as to what course to take as was the doctor himself. It did not seem to be the kind of case which involved the social duty to the husband. The doctor could use his discretion as to whether he would induce the wife to impart the information to her husband. He, the speaker, agreed that in such case marital relations were seriously affected, but there were cases in which, apparently, happy marital conditions continued between the parties, even where one or other party was unable to perform the ordinary marital duties, and there would be a difficulty, in such a case, in supporting such disclosure without the consent of either husband or wife. It differed from the case in which to continue marital relations involved the infliction of cruelty—namely, in imposing on the innocent party the risk of venereal disease.

The question of abortion was of immense medico-legal interest. This practice was very prevalent, and, apart from the actual danger to life, there was the intense agony to which the victims were frequently subjected. It involved two persons; the ordinary case was that in which the doctor was called in to examine the woman who was suffering from the effects of abortion. Everybody must sympathise with the view of that great judge, Justice Hawkins—who had a kind heart—when he said that for the doctor to feel himself under an obligation to give up his patient as having herself committed a criminal offence when she was, perhaps, suffering from peritonitis, would be a monstrous thing. With that the President agreed. If a woman who had been suffering from the effects of abortion could not consult a doctor without being exposed to the risk of being sent to penal servitude, it would mean that more women would die from this cause than at present, and that women suffering in this way would be deprived of humane treatment. But the question arose as to who was the abortionist; the person who carried out the abortion was the one to get at. Though it might be difficult for the doctor to disclose the name of his patient, it might very well happen that he could procure from her the name of the abortionist, and he might be able to give to the police a hint that in a particular—unnamed—case there were grave reasons for suspecting that such a person was carrying on business as a professional abortionist. But it would be a different matter when death was impending.

Lord RIDDELL briefly replied.

ASSOCIATION OF AMERICAN PHYSICIANS.

ANNUAL MEETING.

THE forty-second annual meeting of this Association was held at Atlantic City, N.J., on May 3rd and 4th. Owing to the illness of the President, Dr. C. H. HOOVER, the chair was taken by the Vice-President, Dr. A. S. WARTHIN.

Among the communications submitted were the following:—

Dr. JOSEPH CAPPS (Chicago) read a paper on the

Sensibility to Pain of the Pericardium.

There is, he said, an impression that pain is the most characteristic symptom of pericarditis, but Mackenzie was impressed by the absence of pain in pericarditis without traces of pleurisy. When pain exists it may be dull or sharp; it may be localised or radiate to the shoulder or abdomen. In order to investigate the underlying conditions experimental methods were tried. We used cases with paracentesis and touched the serous pericardium and sac round the heart through the fourth interspace; this caused no pain. When entry was made through the fifth interspace there was pain in the phrenic nerve region of the neck. Four clinical groups were studied: (1) pericarditis with effusion, (2) dry, (3) cases with coronary thrombosis, (4) with pleurisy. In the first group, even with large effusion, there was no pain or respiratory distress. The second type, dry terminal pericarditis, had no pain or distress. The patient died in 36 hours. There was no pain with coronary thrombosis. In pleuro-pericarditis there was sharp pain at the end of inspiration, also pain in shoulder. From an experimental standpoint, therefore, we have been unable to elicit pain from irritation of the serous sac of the pericardium and sheath of the heart. The only pain elicited was by irritation of the phrenic nerve supply through the fifth interspace, which radiated to the neck. Large pericardial effusion caused respiratory distress, but no pain. Pleuro-pericarditis caused sharp pain increased by expiration.

Dr. L. G. ROWNTREE (Rochester, Minn.) contributed studies in

Experimental Thrombosis.

Six or seven per cent. of the surgical deaths in Rochester, he said, are due to pulmonary embolism. We have tried to study this phenomenon by experimental methods, with a view to devising an effective régime for its prevention. We used experimentally a tube with a dialysing membrane, which is put into the vein and the blood flows through without contact with the air. By means of our apparatus we can slow the stream or make it rapid; we can apply heat or cold or chemical substances; we can produce pathological conditions; and we can study extracorporeally thromboses which occur in vivo. We can study what is going on in the tube. We find heat hastens coagulation time and cold retards it. To prevent clotting we used heparin, which is an antiprothrombin. Coagulation is much delayed thereby and clots form slowly, but there is no thrombosis. In jaundiced animals there was great formation of white thrombi but no fibrin. With many platelets, and without fibrin formation, the blood continued to circulate. Thus it is possible to prevent fibrin formation.

Dr. EUGENE S. KILGORE (San Francisco) gave the following communication on

Polycythemia in Feather Dyers.

In July, 1919, there died in the University of California Hospital a German feather dyer (Mr. C. M.), aged 61, who showed clinically a high red count (up to 8,000,000), considerable cyanosis of nose and ears, palpable spleen, some fibrosis of the apex of the right lung, and, terminally, severe substernal and precordial pain, and on autopsy erythroblastic hyperplasia of marrow of long bones, coronary thrombosis, chronic myocarditis, splenic and renal embolism, and fibrous tuberculosis of the right apex. Two years previously the cyanosis and other physical features were the same, but the blood findings were not remarkable (4,416,000 red blood corpuscles). Before his death there came to visit him his assistant in feather-dyeing, Miss M. D., aged 39, who we then learned had been previously seen by Hurwitz and Falconer and as having polycythæmia. She gave them her occupation as milliner, so contact with chemicals was not stated. Her red cells at one time were 12,400,000. She improved following irradiation and benzene treatments. Hurwitz and Falconer reported her symptoms of dizziness, &c., as we now learn, from about the time she began dyeing, and her improvement corresponded not only with treatment but with her occupation becoming intermittent. After nine years it has ceased, and she is in excellent health with normal blood count. Owing to changes in fashion only one feather dyer remains in active work in San Francisco, a middle-aged Japanese man. He has 70 per cent. hæmoglobin (Tallquist)—6,040,000 red and 7800 whites. Feather dyers appear to be more exposed than cloth dyers to atmospheric spraying of the chemicals, as they shake the feathers on removing them from the dye-bath. Records of 12 cases of polycythæmia are recorded in the University of California Hospital since 1913—four attributable to congenital heart disease, one to emphysema, one to tricuspid disease. Two are the feather dyers referred to above, one a man who for many years dyed his hair black, the other three cases have had no dye contact, but the finding of a red count of 6,000,000 in the only surviving feather dyer in San Francisco makes it necessary to regard chemical contacts as more than coincidental. A. Hamilton (Industrial Poisons in the United States) reviews reports of workers, exposed to carbon monoxide, methyl alcohol, and ether in whom polycythæmia was noted. Malden reported 6 out of 13 workers in aniline fumes with blood counts over 5,000,000. The highest was 5,680,000. The increased concentration of red cells in all these cases has been regarded in a general way as due to primary destructive action of the poisons, with secondary stimulation of erythroblastic elements. Evidently, however, the study of dyestuffs in this connexion must be carried further. Feather dyers used mainly coal-tar derivatives. If the aniline series was responsible for the blood changes it is possible that different members of the series are not equally effective, and it is possible that the increased cell production is not simply a secondary effect of long-continued destructive action, but a primary or predominant effect of one or more of the substances, and that therapeutic use of them might be obtained.

Dr. ALBERT E. TAUSSIG (St. Louis) spoke on

Diabetes Mellitus Refractory to Insulin,

reporting cases unresponsive to doses of insulin. It has been suggested, he said, that this is not pancreatic diabetes. A patient in the Jewish Hospital, St. Louis, in 1922 had a progressively severe diabetes and showed urticaria after injections of insulin. She went into diabetic coma and enormous doses of insulin were given without making her sugar-free. One day she had 1100 units of insulin. In patients who showed little or no drop after intravenous injections hypodermic injections were tried with no better result, nor were fractional doses of 20 units hourly more successful. After two months the response to insulin showed improvement and finally it was possible to give a daily dose of 200 units. Finally the insulin was brought down to 104 units daily. The woman is able to work as a teacher. To find the reason for this refractory condition 10 c.cm. of the patient's blood were injected into rabbits, but there was no result. Tests for an allergic skin reaction gave no result; there was no trace of insulin in the urine. The theory that insulin acts as a co-ferment, transforming blood-sugar into glycogen or lactic acid, was considered. In some persons the other constituent (muscle phosphate) may

be lacking or may be present in too small amounts, so that insulin is not able to do its work.

Dr. F. M. ALLEN (Morristown, N.J.) described

Myrtillin, a Diabetic Remedy Orally Administered.

He stated that a wide variety of vegetable substances have been tried in diabetes. Myrtillin has given varying results in dogs. There are two substances present in association: (1) myrtillin, which lowers blood-sugar; (2) a substance which raises it. These two substances occur in all plants and belong to the anabolic-catabolic activities of plants. If myrtillin is effective at all it is as effective in doses of 1 g. per day as in doses of 30 g. The effect is to stabilise blood-sugar reactions when administered orally. Myrtillin is standardised by reactions in dogs. The results are the same when given by mouth or by vein, the effect lasting for days or even weeks. The effects in dogs can be duplicated in patients with mild diabetes, but cannot be demonstrated in the rabbit or the rat. Experiments on dogs show that these animals cannot survive depancreatisation more than a week; functions are depressed, resistance lowered, infections cannot be cured, wounds do not heal. When myrtillin is used, started one day before operation, pancreatectomy is performed, and the animals are then fed on meat, milk, and bread, they hold their weight and maintain strength. They play and fight, and seem lively, the wound heals, and minor infections are overcome. The myrtillin-treated dogs are generally superior to insulin-treated dogs. Life can be maintained for some weeks or indefinitely. The experiment of partial pancreatectomy is better because it resembles human diabetes. With nine-tenths of the pancreas removed there is severe diabetes, which can be controlled by myrtillin. If only one-fiftieth of the pancreas is left the animals cannot survive even with myrtillin. Autopsy shows hypertrophy of the pancreas remnant. The first step in therapy is to make the urine and blood normal with insulin or diet, and then to give myrtillin and then watch for gradual building up of tolerance. It is necessary to use patients who have been studied over a number of years to guard against spontaneous gain in tolerance. In a series of 81 this condition excluded 24 patients, and of the remaining 57 21 were failures, 36 were positively benefited, 6 patients had never received insulin, and 15 patients were able to reduce insulin and increase diet. The remaining six patients were able to discontinue insulin.

Conclusions.—Myrtillin can be administered orally. It is harmless. It builds up tolerance. On the other hand, it is less prompt, less powerful, and less certain than insulin. It has a certain number of failures. The method deserves clinical trial, but should not be considered as a substitute for insulin.

Dr. JOHN F. ANERSON (Washington, D. C.) spoke in confirmation of Dr. Allen's results. He said that the work was begun in 1926. Myrtillin was prepared from blueberry leaves, extracted by 6 per cent. alcohol solution, and the protein removed by further precipitation. A clear filtrate contains the preparation, which is a yellowish white powder freely soluble in water. It contains traces of sulphate of ammonium chloride, iron, magnesium, calcium, sodium. In the experiments were used (1) normal dogs, plus myrtillin, plus glucose; (2) totally depancreatised dogs, without myrtillin; (3) totally depancreatised dogs, with ten days of myrtillin. In the first experiments were got normal curves for individual dogs. Blood samples were taken, then 1 g. myrtillin was given, followed by 10 g. glucose per kilo body-weight. Thirty-eight dogs were studied. The administration of myrtillin before glucose prevented a sharp rise in blood-sugar. The result persisted for 15 days with gradually lessening effect. The blood-sugar later returned to normal after myrtillin. The results in the total pancreatectomy were: myrtillin 24 hours after operation; 1 g. myrtillin every morning; 200–500 g. meat, 20 g. white bread. Result: loss of weight until death, temperature normal, blood-sugar 200 to 300 mg. per 100 c.cm., at death 400 mg. The animals were lively, hungry, had no excessive thirst; duration of life 21 to 61 days. In the third experiment 1 g. myrtillin by mouth was given ten days before operation; four dogs were used and survived 21–48 days. The results were the same as in the previous operation. In the fourth experiment without insulin or myrtillin the animals died in a few days and wounds did not heal.

In regard to the clinical side of the work 16 patients with long-standing diabetes and under care of physicians were studied. In two cases there was remarkable improvement; one showed no benefit; in two patients on insulin the amount of insulin was decreased (60 units to 20 and 20 units to 5). These results were corroborated by another physician. One patient had influenza and had to increase insulin temporarily, but later was able to reduce the amount again.

Dr. J. C. MEAKINS (Montreal) discussed the

Reaction of Chronic Nephrosis to Thyroid and Parathyroid Medication.

Improvement has been noted, he said, in nephrosis as a response to thyroid and parathyroid medication. The effect is due to the readjustment of the calcium metabolism which has been studied. In a woman, aged 33, with recurrent attacks of œdema which was resistant to diuretics, the patient was put on thyroid medication with good result. The urine contained casts and red cells. The urea was normal. The blood calcium was low. Put on parathyroid extract, 50 units a day, there was a prompt increase in serum calcium, marked increase in urine output, and drop in weight. When the parathyroid was stopped the œdema returned. In another case, a girl with œdema and ascites, and a reverse of the albumin globulin ratio, there was an increase in blood cholesterin, the blood calcium being low. There was no response until the eighth day. This was a case of mixed glomerular nephritis with nephrosis. In another case a man, aged 24, with œdema, the parathyroid had no effect on the weight. With high protein diet there was response in weight, but none in the plasma protein. A drop in weight followed thyroid medication. The cholesterin in the blood dropped. There is evidently an endocrine imbalance in these cases which varies in different patients; sometimes thyroid is effective, sometimes parathyroid. Sometimes it is not due to calcium disturbance. The plasma proteins may not be changed. We must look elsewhere than the colloids of the blood for explanation of an œdema which is refractory.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT a recent meeting of this Society, held at Sheffield, with Dr. CARLTON OLDFIELD in the chair,

Miss FRANCES IVENS (Liverpool) read a paper on

LATENT SEPSIS AS A FACTOR IN THE ÆTIOLOGY OF THE TOXÆMIAS OF PREGNANCY.

Previously,[1] Miss Ivens said, she had drawn attention to the association of latent infection with the œdema and albuminuria of pregnancy, the occurrence of which was, she thought, an indication for the bacteriological examination of the urine, even in the absence of urinary symptoms. The toxæmias of pregnancy—œdema, albuminuria, hyperemesis, accidental hæmorrhage, jaundice, and eclampsia—were closely allied, and a common factor was present in all. Biochemical research had been disappointing and a bacterial origin appeared to be most probable. A series of cases investigated had been classified into four groups:—

(*A*) *Albuminuria and Œdema.*

Thirteen pregnant women with these symptoms were under care during the last two years at the Liverpool Maternity Home. In these cases the presence of coliform organisms with pus, and some-

[1] Brit. Med. Jour., 1925, i., 589.

times blood, was demonstrated in the urine. The patients were treated by rest in bed, rectal salines, calomel, saline purgatives, and potassium citrate in large doses. Only one patient, who was allowed to go home before delivery, had a stillborn child.

In 21 cases examined bacteriologically at Crofton Hospital 7 cases showed *Bacillus coli*, 2 a non-hæmolytic streptococcus, and 11 *Staphylococcus albus*, whilst in one the urine was sterile.

(B) Hyperemesis Gravidarum.

CASE 1.—A primipara vomited constantly throughout her pregnancy. The urine contained albumin, red cells, pus cells, and coliform bacilli. In addition there was an abscess of Skene's glands. The temperature was 101° F. and the pulse-rate 130. Rectal salines and potassium citrate were given in large doses and 10 c.cm. anti-coli serum were also given. A premature infant was born and lived 16 hours. The vomiting continued after delivery, with raised temperature and pulse. After vaccine treatment the patient was discharged in three months with the urine practically normal and the general condition excellent.

CASE 2.—A 2-para had had vomiting throughout her first pregnancy and had been prematurely delivered of a child, which died on the fourth day. In the second pregnancy she was well for the first three months. She then vomited incessantly. On admission the temperature was 99·8° F. and the pulse-rate 110. The patient became comatose and the vomit hæmorrhagic. The urine contained albumin, coliform organisms, and acetone and diacetic acid. A Cæsarean section was done at 26 weeks, owing to her serious condition. She quickly recovered.

(C) Jaundice.

CASE 3.—A 3-gravida was admitted with vomiting, jaundice, and retention of urine at eight months gestation. The urine contained pus, bile, and *B. coli*. After treatment with purgatives, potassium citrate, and salines improvement was marked. Labour started with excessive bleeding, but the child was born alive, though jaundiced. Rigors followed delivery with an attack of right-sided pyelonephritis. On discharge the urine was normal. It was probable that in this case, in addition to infection of the urinary tract, infection had spread to the biliary passages.

CASE 4.—A 6-gravida always vomited severely during pregnancy. Five days before confinement she vomited blood-stained material. On admission she was jaundiced; the temperature was 97° F. and the pulse-rate 120. The urine contained albumin, pus, coliform bacilli, acetone, and bile. A blood culture was sterile. A macerated fœtus was delivered after internal version for transverse lie and prolapsed cord. 10 c.cm. of antistreptococcal serum was given and rectal salines. She was quite well on discharge from hospital in a fortnight's time.

(D) Accidental Hæmorrhage.

CASE 5.—3-gravida. A Cæsarean section was performed in 1924 for contracted pelvis. In 1926 she was delivered by Cæsarean section for severe antepartum hæmorrhage. There was blood-stained fluid in the peritoneal cavity. There were hæmorrhages into the wall of the uterus. The child was dead. The urine contained a trace of albumin, coliform organisms, and streptococci. Coliform organisms were cultivated from the placenta. In 1927 a third Cæsarean section was performed. The urine was normal and the patient appeared perfectly healthy.

CASE 6.—A 5-gravida. The first three pregnancies and deliveries were normal. In labour with the fourth child there was concealed accidental hæmorrhage. She was delivered of a dead child by Cæsarean section. There was hæmorrhage into the wall of the uterus. The urine contained pus and coliform bacilli. With her last pregnancy in 1925 labour was premature. She had œdema and vomiting for five weeks previously. The urine contained albumin, coliform organisms, and streptococci. The placenta showed areas of white infarction and round-celled infiltration.

CASE 7.—A 6-gravida delivered by Cæsarean section, for placenta prævia, of a child, weight 4 lb. 5 oz. Hæmolytic streptoccocci and staphylococci were found in the wound. The urine contained a trace of albumin and staphylococci. The child died on the fifth day after hæmorrhage from the mouth and nose.

CASE 8.—An 8-gravida was admitted almost moribund with antepartum hæmorrhage. High forceps delivery of a macerated fœtus. The patient died soon after delivery. Cultures from the placenta grew coliform bacilli and streptococci. No urine was obtainable for examination.

CASE 9.—A 7-gravida was admitted with concealed accidental hæmorrhage and Cæsarean section was performed. There was blood-stained fluid in the peritoneal cavity and the uterus showed intramural hæmorrhages. The child was dead and the patient died immediately after operation. The urine contained albumin, staphylococci, and streptococci. The placenta gave growths of *S. albus* and non-hæmolytic streptococcus. A varicose ulcer on the patient's leg contained *S. albus*. The maternal liver showed hyaline thrombi. The kidneys contained hyaline thrombi with areas of coagulation-necrosis, and the uterine muscle stained badly, showing presence of hæmorrhages.

In conclusion, Miss Ivens said that she had hoped to stimulate interest in the bacteriological investigation of similar cases, for she was convinced that latent and autogenous infection played a great part in the ætiology of the toxæmias of pregnancy, especially where there was lowered resistance during pregnancy and where patients were delivered with trauma. She considered it necessary to obtain a full life-history of these patients, and to look for evidence of foci of infection in the throat, gums, and elsewhere.

She was indebted to Prof. J. M. Beattie, Dr. L. S. Ashcroft, and others who had assisted in the bacteriological investigation.

Discussion.

The CHAIRMAN said that urinary infections were very commonly associated with albuminuria. There was a danger of assuming, when organisms were present, that they were the cause, when in reality they were the result, of a certain pathological condition. He still was of the opinion that hyperemesis gravidarum was not due to a toxæmia.

Mr. A. GOUGH (Leeds) said that it was not sufficiently realised by practitioners how often the genito-urinary tract was infected. In 100 gynæcological cases examined bacteriologically by him cultures of bacteria were grown in 70, of which 10 were growths of *B. coli*. He explained the preponderance of infection by *B. coli* by the fact that it was a mobile organism capable of swimming up-stream, and able to proliferate rapidly.

Mr. J. E. STACEY said that at the Jessop Hospital, Sheffield, they had been struck with the number of cases of morbidity during the puerperium in patients with albuminuria during pregnancy and labour.

Dr. S. B. HERD (Liverpool) asked if there was any definite association in Miss Ivens's cases between sepsis during pregnancy and morbidity during labour and the puerperium.

In reply, Miss IVENS said that she had noticed that patients with latent sepsis did not do so well in the puerperium as others did.

EXHIBITION OF CASES.

Dr. HERD described a case of pregnancy complicated by

Necrobiotic Fibromyoma and Accidental Hæmorrhage.

The patient, a primigravida, was first examined when 12 weeks pregnant, and a soft non-tender swelling was noticed high up on the right side of the uterus. This was diagnosed as a subserous fibroid. At 17 weeks the patient had acute dysuria and a feeling of great pressure in the vagina and region of the symphysis pubis. On examination the uterus was felt to be displaced by a hard, tender mass fixed in the right side of the pelvis. A diagnosis of degeneration of the fibroid was made.

As it was impossible to move the tumour under anæsthesia the abdomen was opened and a degenerated fibroid was removed from the uterine wall just above the right utero-sacral ligament with some difficulty and not without a great deal of manipulation of the body of the uterus. No other fibroids were present. The patient was kept under morphia for a few days to diminish the chances of abortion, and this treatment succeeded. On the fifth day there was thrombosis in the right leg, which was believed to be due to lack of the exercises which had been ordered.

She remained quite well until 32 weeks gestation, when she developed a violent headache. On the next day the perception of fœtal movements ceased and she had slight œdema. Two days later there was marked œdema and albumin 16 g. per litre in the urine. The fœtal heart sounds were heard on that day. Two days later there was sudden onset of pain and vaginal hæmorrhage; morphia was administered. Three days later a slightly macerated fœtus was delivered. The puerperium was normal.

The special points in this case, said Dr. Herd, were the persistence of the pregnancy after marked

manipulation of the uterus, the supervention of toxæmia followed by accidental hæmorrhage, and the fact that the fœtal heart was heard for three days after the perception of movements had been lost.

The PRESIDENT said that he did not think that the lack of exercises should be blamed for the thrombosis. He suggested that the necrobiosis in the fibroid had produced toxæmia in the first place, causing a retro-placental clot which led to placental changes which later gave rise to albuminuria and accidental hæmorrhage.—Dr. E. O. CROFT (Leeds) said that it was surprising how much manipulation a pregnant uterus would stand without aborting, and recalled a similar case of myomectomy.—Mr. J. E. STACEY asked what would have happened if operation had not been performed. He had seen a case of pregnancy with a large fibroid in the fundus in which there had been symptoms at seven months gestation. It was treated expectantly and settled down. The patient had a placenta prævia, and the child was stillborn. On the ninth day of the puerperium symptoms again arose, and myomectomy was successfully performed.—Miss IVENS recalled a case which three weeks before term induction was attempted by bougie for a contracted pelvis. Introduction of a bougie produced severe bleeding and it was withdrawn. At term Cæsarean section was performed and a large retro-placental clot was found. There had been no albuminuria in the meantime.—Mr. W. GOUGH (Leeds) related a case in which a fibroid the size of a hazel nut gave rise to such severe pain during pregnancy that operative treatment had to be undertaken. Myomectomy cured the condition.

Dr. HERD, in reply, said that there was an interval of 14 weeks between the operation of myomectomy and the onset of the albuminuria; he submitted that this was too long for the albuminuria to be due either to the necrobiosis or to retroplacental clot caused by the manipulation of the uterus. In this case the position of the degenerated fibroid would have obstructed labour even at the early period of 18 weeks gestation, so operation had been essential.

Mr. A. GOUGH (Leeds) described a case of

Pelvic Myxoma.

The patient, aged 35, was a multipara. She had noticed a swelling in the left gluteal region at least 12 years previously, and others had later formed in the abdomen, perineum, and vulva. Four operations had been performed between 1915 and 1924, during one of which the large gut had been damaged, necessitating a colostomy which only closed several months later. Menstruation was normal and the functions of the bladder and rectum were unimpaired.

There was a mass filling the left lower quadrant of the abdomen. The tumour could be traced over the pubis to the left labium majus, where it formed a huge pedunculated mass hanging down nearly as far as the knees. The circumference was 5½ in. in the upper part and 22 in. at the lower end; the total length from the pubes was 11 in. The overlying skin was thinned and purplish. The tumour could be traced backwards into the left buttock, where there was a mass the size of an adult head. The tumour was painless and felt spongy and elastic with some coarse lobulation. Vaginal examination was unsatisfactory, but the left side of the pelvis was felt to be full of growth continuous with the superficial masses and displacing the vagina and rectum to the right.

Complete removal was impossible. At the first operation the pendulous portion was removed at its origin at the level of the pubes; it weighed 5 lb. 1½ oz. Four months later the gluteal mass was removed. Cystic spaces were noted in both masses. Microscopical examination showed typical myxomatous structure. The cystic spaces were bounded by layer of condensed stroma, no epithelial lining being demonstrable.

The PRESIDENT said that it was very difficult to deal with these cases. He had operated on one of them several times. He suggested deep X ray therapy.

Mr. GOUGH said that he had discussed X ray therapy with a radiologist who had expressed the opinion that it was useless in these cases. Mr. Gough also described a case of a large solid ovarian tumour with twisted pedicle.

Mr. STACEY showed calculi removed from a case of complete procidentia.

Reviews and Notices of Books.

THE CONSERVATION OF THE FAMILY.

By PAUL POPENOE. London: Ballière, Tindall and Cox. 1926. Pp. 266. 13*s.* 6*d.*

THE reader is informed in a preface that this work is the sequel of another which was devoted to the problem of marriage as it confronts the individual in a private capacity. This book is held to supplement the first in that it is concerned with the things the individual cannot do for himself, but which it should be the duty of society to do for him. As is implied by the name, this book is eugenic in object. It is divided into four parts. In the first is described what the author holds to be the normal family—upon the conservation of which the future of America will depend. The ideal family is monogamic in constitution, and should be entered upon early in life by both parties. These should belong to strains exhibiting health, vigour, longevity, and socially valuable mental qualities. The children should number at least four, and in superior families the figure should be exceeded. In the second part of the book are described those conditions which in America interfere with the normal functioning of the family as previously described. Abundant statistics are furnished to support the contention of each chapter. Celibacy and the ascetic ideal are condemned as dysgenic. Figures indicating the prevalence of premarital incontinence, obtained from American undergraduates of both sexes, suggest that America is more fertile in material for the statistician of these subjects than this country. The breaking of homes, the frequency of which is measured by the number of divorces, is attributed in large part to the prevalence in America of the romantic ideal of love, which is held to have emanated from the Orient. To the exhaustion of this sentiment, which is expected to persist throughout conjugal life, is attributed the failure of so many marriages. Prostitution, delayed marriages, venereal diseases, infertility, abortions, inadequate reproduction among superior types, and excessive reproduction among inferior families are the subjects of separate chapters, and are held to oppose the conservation of the normal family.

The third part of the book deals with the methods of social control by which the family may be preserved. The education of adults to their parental responsibilities, and a change of public opinion with regard to childbearing and the family are the first of the necessary changes. In dealing with economic reforms, the author opposes the taxation of bachelors and childless married couples, the undiscriminating family wage, baby bounties, and maternity benefits. On the other hand, he favours a family allowance depending in magnitude upon the basal pay of the father. Thus, if an increase of 10 per cent. were made to the wages of a father of a family as each child was born, the artisan would receive a larger increment than the unskilled labourer. Such a graduated subsidy could never become a mere incentive to the socially useless members of society to multiply. It is said that this system is in effect among civil servant employees in Holland. Preferential employment for married men with children is naturally advocated; the author also propounds a scheme intended to counteract the tendency to late marriages among superior parents. It consists in an inversion of the usual method of life insurance. In the words of Dr. Noyes: "To enable picked individuals to marry earlier, why not reverse the ordinary policy of insurance in which a small sum is paid to the company for a long series of years, and at death a large sum is paid to the relation, and in its stead let the company advance the large sums first in quarterly or monthly instalments for a short series of years, decreasing gradually to nothing . . . and then let him pay into the company a small sum for a long series of years?" Lastly, the author advocates urban decentralisation, and the

migration of all who can afford it to the country and the farm.

In order to diminish the reproduction of inferior families, the author suggests that clinics be founded where the methods of contraception that are most approved should be taught. The grossly defective should be sent to farm colonies wherein the sexes are segregated, and which, under proper management, should be self-supporting. And the author would like to see courses in maternity and child welfare established for young women at American universities.

The book is marred in parts by careless writing, by a certain crudity of argument, especially evident in the selection of analogies, by which the author reduces to absurdity the contentions of his opponents, and by a tendency either to ridicule or to dismiss as unworthy of serious consideration views that do not assort with his own; but it is well-compiled, well-stocked with references to other works on kindred subjects, and is never dull.

FOOD AND THE PRINCIPLES OF DIETETICS.

Sixth edition. By ROBERT HUTCHISON, M.D., F.R.C.P., Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street. London: Edward Arnold and Co. 1927. Pp. 610. 21*s*.

THE alterations in the new edition are few but important. Some account of the sippy treatment of peptic ulcer has been added, and the sections dealing with vitamins and infant feeding have been modified. Except for minor details the remainder of the text is unchanged. This book has long been a classic in the modern science of dietetics. First published in 1900, its origin was a course of lectures delivered to students of the London Hospital. At that time the subject of dietetics was almost wholly ignored in the curriculum, and even now, though isolated facts of food metabolism and the effect of deficient diets are taught, the student who is to be a successful practitioner must gain a better working knowledge of the preparation and value of foodstuffs than he will find in text-books of physiology, hygiene, or medicine. All that he needs he will find attractively presented by Dr. Hutchison.

FORENSIC PSYCHIATRY.

An Introduction to Forensic Psychiatry in the Criminal Courts. By W. NORWOOD EAST, M.D., Medical Inspector, H.M. Prisons, England and Wales. London: J. and A. Churchill. 1927. Pp. 381. 16*s*.

MANY medical practitioners may find themselves at a disadvantage when called upon to give evidence in the criminal courts upon the issue of mental disease. The text-books on insanity and mental deficiency seldom deal with points of practice and procedure, and often the prospective witness cannot spare the time in which to search a library. For his benefit Dr. Norwood East has put on record the experience he has gained during many years' work as medical inspector of H.M. Prisons and in constant appearances in the witness-box at criminal trials. He begins with two excellent chapters on Ascertainment and on Practice and Procedure which contain much information not readily to be found elsewhere. His readers will gather useful hints on how to deal with the stock questions of the cross-examiner, and they will be prepared also for those casual questions from the Bench—not necessarily relevant to the issue, often unexpected and occasionally disconcerting, as when a medical witness is suddenly asked by the judge to express an opinion upon the sterilisation of the insane.

The chapter on Criminal Responsibility is a careful and correct summary of the history and present condition of the law. Dr. East's official experiences and associations have led him rather to bridge than to widen the gap between legal and medical opinion. Without disguising the fact that the law often seems to lag behind the progress of modern medical science, he states his conclusion that the legal tests of insanity work no hardship to the accused because the law is not strictly applied. Like the late Dr. Mercier, he finds after prolonged study of reported cases remarkably few instances in which an accused person has been convicted upon evidence which appeared to justify acquittal on the ground of insanity. Dr. East goes so far as to doubt whether alteration of the law might not result in its less elastic administration and consequently in more obvious hardship to the accused. In subsequent chapters Dr. East classifies and expounds the several types of insanity. The illustrative cases are well chosen and are aptly and scientifically stated—needless to say, without the faintest trace of sensationalism. This book is the work of an expert, writing upon a subject which he has made his own, knowing what he wants to say about it, and able to say it clearly.

DISEASES OF INFANTS AND CHILDREN.

Second edition. By J. P. CROZER GRIFFITH, M.D., and A. GRAEME MITCHELL, M.D. London and Philadelphia: W. B. Saunders Company, Ltd. 1927. In 2 volumes. Pp. 1715. £4 10*s*. per set.

THE first edition of Prof. Griffith's comprehensive work on pediatrics, which appeared in 1919, has lately been out of print, and the author has produced an enlarged and revised edition in collaboration with Prof. Graeme Mitchell of Cincinnati. The form of the original work has been retained, but new material has been incorporated throughout the text, and a number of new articles have been included, the size of each volume being somewhat increased. Among the more notable additions are new sections on encephalitis, allergy, and spasmophilia, which are of the same high standard as the older parts of the book. The chapter on infant feeding has undergone some modification, and those on rickets and congenital syphilis are greatly amplified. In general the lines of treatment followed by the author in the first edition have suffered little change. The illustrations and colour-plates are, as before, a notable feature. This book should be of the greatest assistance as a work of reference for post-graduate students, to whom its value will be much increased by the comprehensive and well-chosen list of references to original papers. This list has been brought fully up to date, and forms one of the best bibliographies available on this subject.

MODERN PRACTICE OF PEDIATRICS.

By WILLIAM PALMER LUCAS, M.D., Professor of Pediatrics, University of California. London: J. and A. Churchill. 1927. Pp. 962. 30*s*.

THE increasing attention which the study of pedia-trics has claimed in recent years is evidenced by the quality as well as the quantity of the text-books which appear on this subject. Prof. Lucas's work, though it covers well-worn ground, has many distinctive features which will recommend it to the reader. It contains in one volume both a comprehensive account of the physiology and biochemistry of early life, and a clear and readable description of the clinical aspect of children's disease, with a very successful attempt to correlate the two.

The first part of the book is largely concerned with physiology and metabolism, and contains a remarkably clear account of involved problems such as arise out of the work of Finkelstein and Czerny. The second part is devoted more fully to disease, but pays special attention to the development of the child and to mental problems. The practical value of the work is increased by a chapter containing details of diagnostic and therapeutic measures, and by lists of references appended to each chapter. The latter would be of still greater assistance to the student if their precise connexion with the text were indicated by reference numbers. The volume may be recommended as an admirable text-book for senior students and practitioners.

A TEXT-BOOK OF BACTERIOLOGY FOR DENTAL STUDENTS.

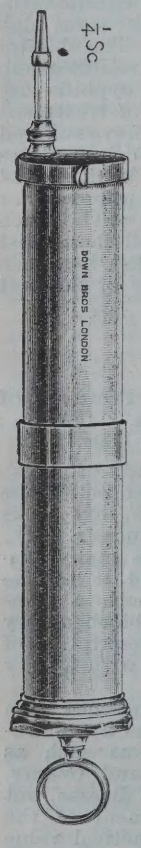
By ARTHUR BULLEID, L.R.C.P., M.R.C.S., L.D.S., Assistant Dental Surgeon and Assistant Bacteriologist to Guy's Hospital. London: Heinemann. 1926. Pp. 219. 15*s*.

IN his preface Mr. Bulleid states that the book has expressly been termed a text-book of bacteriology for dental students rather than a text-book of dental bacteriology. The distinction is important, for while it may be conceded that the dental student does not need to know the outlines of general bacteriology in such detail as does the medical student, yet a sound knowledge of general bacteriological principles is essential if he is to be able to understand the more limited bacteriology of the mouth. Many of the books on bacteriology written for dental students fail in this respect. Either they consist of a few severely abbreviated chapters on general bacteriology with a fuller account of the flora of the mouth, or else the book is devoted exclusively to the dental aspects of the subject. The latter type of book is justified if it be regarded as an advanced book for the specialist who has already a grounding in general bacteriology, but the former type is almost useless, for it fails to emphasise the general principles essential to a grasp of the application of such problems as immunity, infection, or inoculation to dental disease. Mr. Bulleid's book steers clear of these pitfalls, the balance being maintained between the general and the special aspects of bacteriology. Indeed, the medical student may find it useful, not as a substitute for the larger text-books, but as a supplement giving a clear account of the organisms of the mouth in their relation to dental disease. The chapters on cultural methods, staining methods, susceptibility, and immunity are all excellently written and convey clearly the chief points of importance. A fuller account of the principles underlying such a phenomenon as agglutination would have been welcome. We miss any reference to Besredka's views on local immunity; the more so since this has been made the basis of a special method of bacterial therapy for pyorrhœa. The book deserves a wide success.

New Inventions.

A SIMPLE METHOD OF BLOOD TRANSFUSION.

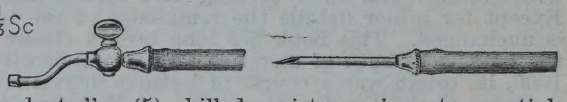
THE use of a large glass syringe was a big step towards simplifying the technique of blood transfusion. Glass syringes, however, are fragile, they lack perfect apposition of piston and barrel, and they are necessarily limited in capacity. Their disadvantages have been overcome in the method here described.



The apparatus illustrated consists of a metal cylinder (11¾ in. long by 2 in. diameter) which holds 1 pint; and there is a metal piston, and an excentrically-placed glass and metal nozzle. Rubber tubing is incorporated between the nozzle and the needle to act as a shock absorber. The nozzle should be sterilised with alcohol, but must be thoroughly dried before use. The rest of the apparatus is boiled. The piston is smeared with a minute quantity of sterile vaseline. When the syringe and needle are assembled, 2 drachms of a sterile saturated solution of sodium citrate are drawn in through the needle and allowed to play over the whole of the interior of the syringe. The air is expelled from the syringe and the needle is inserted into the donor's vein. An assistant aspirates whilst the operator holds the needle steady. When the syringe is full the needle is withdrawn. If a larger transfusion is required the needle, with attached tubing, is left in the vein, and the nozzle of the second syringe is attached to it. Alternatively, each of the syringes may be filled with blood from different donors. The syringeful of blood will keep unclotted indefinitely, and, if it has been allowed to cool, can be warmed by immersing it in hot water.

For infusion the syringe is held vertically, and any air driven out through the glass nozzle. A small needle, fixed into one end of a piece of rubber tubing, is inserted into the recipient's vein. When the blood runs out of its free end, the tubing is connected to the nozzle. The assistant then presses the plunger, forcing the blood into the vein. Owing to the large pressure that can be obtained, needles of small bore can be used. To withdraw blood, size 15 is recommended. For infusion, size 21 suffices—the size which is used as a routine in this hospital for the administrations of N.A.B. in antisyphilitic treatment.

The following advantages are combined in this method: (1) small quantity of encipient used; (2) the blood is the whole time enclosed in a sterile container; (3) ease and quickness of sterilisation—an autoclave unnecessary; (4) elimination of multiple



"gadgets"; (5) skilled assistance is not essential; (6) transportability; (7) ease of insertion of small needle diminishes number of times vein of recipient has to be cut down on.

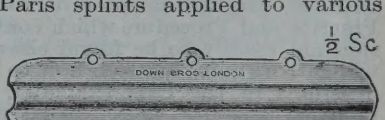
Using the Wolff's bottle method, I have had one case, seen two others, and heard of several more, in which it was necessary to expose the contracted median basilic vein of moribund patients, and it was found impossible to pump blood into the vein after the needle had been inserted. This tonic contraction is made worse by injury to the vein, and is seen only in gravely exsanguinated patients. It is hoped that it will be overcome by the increased pressure obtainable from the syringe. A series of different-sized cannulæ have been designed for the rare cases in which it is necessary to cut down on the vein. The cannulæ are fitted with stopcocks and have bulbous ends to allow of their being tied securely into the vein.

The apparatus was made for me by Messrs. Down Bros., Ltd., St. Thomas's-street, London, S.E.

R. R. MACINTOSH, M.R.C.S. Eng.,
Assistant Medical Officer, Venereal Diseases Department, Guy's Hospital.

A DEVICE FOR CUTTING PLASTER-OF-PARIS SPLINTS.

I HAVE been using with success in India for a considerable time the device illustrated here for cutting plaster-of-Paris splints applied to various parts of the body. The advantages claimed are: (1) it is simple and can be easily and cheaply manufactured; (2) its easy applicability to any part; (3) its lightness; (4) it is very easily applied by fixing it to the jaconette or lint or any other material which envelopes the part with a few stitches before applying the plaster bandages; (5) the rapidity and ease which a plaster case can be cut by interposing one or more of the plaster saws if it is desired to cut in one or more places.



A. F. WINNINGTON DA COSTA, L.M.S. Bombay, D.T.M. Calcutta.

THE LANCET.

LONDON, SATURDAY, JULY 2, 1927.

PROFESSIONAL SECRECY.

THE medical practitioner's obligation to secrecy depends not on legal sanctions but on the ancient tradition of an honourable profession. In our law courts the confidential relation of doctor and patient is cited as a thing well known and understood, but occasion has seldom arisen for it to be explained or enforced. The lack of leading cases on the subject is —as Lord RIDDELL observes in the address published on another page—highly creditable to the medical profession. If the traditional obligation had been frequently or flagrantly dishonoured, the law reports would have recorded the remedies which the judges would have felt obliged to grant. As it is, the law is definite upon a few points only. Doctors must notify infectious disease, for instance; they must certify the cause of death; and they cannot withhold their answers on any plea of privilege when required to give evidence by a competent court. But, apart from these and similar exceptions, medical secrecy though recognised in law is not founded on law. Indeed, it does not fit comfortably into legal theory. If the obligation of secrecy is part of an implied contract between doctor and patient, how are we to account for the obligation (equally strong) between a doctor and a hospital patient with whom he has no contractual relation? The analogy of the legal profession is not entirely satisfactory. A lawyer, in the sense that he may have to defend his client from a charge of murder, may be said to be concerned to save his client's life; but in general the services which a solicitor or barrister renders for the preservation of rights and property, important as they may be, are hardly of the same personal and individual nature as the services by which doctor or surgeon preserves health and vitality. A client would probably suffer less by asking his legal adviser for an opinion upon an abstract point of law than a patient by asking his medical adviser's opinion upon an abstract question of health. Legal professional secrecy is entitled to absolute privilege in a court of justice, the principle being based on the expediency of securing to everyone the full protection of the laws. It is equally expedient that everyone should have the full benefit of protection from pain and disease, yet the medical profession has no privilege. Clearly the relationship of solicitor and client is an imperfect and fallible guide to the legal position of doctor and patient.

But if the legal position is obscure, there is seldom any doubt in practice whether the doctor should observe reticence or disclose the information he has acquired, though, of course, it is no part of a doctor's duty to cover the tracks of a criminal. Lord RIDDELL has postulated certain cases for the sake of argument. In some of these it will be found that, if disclosure seems justifiable on ethical or social grounds, the medical practitioner's rôle is not to make the disclosure himself but to persuade the patient to make it. In cases of doubt, reticence should have the benefit of the doubt. Even in the witness-box where—as Lord BIRKENHEAD has so elaborately explained—the doctor is not allowed to refuse to reply to the questions of the court, he should make his respectful protest and strive to reduce to the minimum the information he is called upon to give. The court holds over him in the last resort the power to commit for contempt the witness who refuses to reply. But commitment is by no means inevitable. Thirty years ago (in KITSON *v.* PLAYFAIR) Mr. Justice HAWKINS stated that a judge might refuse to commit a medical man for contempt in declining to reveal confidences; "every case must be governed by particular circumstances." Lord Justice ATKIN observed the other day that judges should, and do, exercise a reasonable discretion in enforcing disclosure or not. He emphasised the known difficulty of ensuring satisfactory treatment of venereal disease in the absence of an absolute guarantee of secrecy. As is stated in "The Conduct of Medical Practice," it is the patients and not their medical advisers who would derive advantage if the revelation of medical secrets in the witness-box were prevented. It is strange that the public has never insisted upon a change in the law and upon the establishment of an absolute duty of medical secrecy in the law courts—a duty which would be by no means repugnant to the medical profession.

PUBLIC HEALTH IN SCOTLAND.

THE annual report[1] of the Scottish Board of Health for 1926 contains, as usual, much interesting matter. Reference is made in its several chapters to all the activities over which the Board exercises supervision, including national health insurance, Poor-law administration, old age pensions, welfare of the blind, and so forth, in addition to that part of public health administration the executive control of which is in the hands of local authorities. This is not a dry-as-dust blue book, but a readable account of statistical and administrative facts, with occasional reflection on their significance.

One of the most striking features of the mortality statistics of Western Europe in recent years has been the steady decline in the death-rate from tuberculosis, and nowhere has this tendency been more marked than in Scotland. The death-rate per 100,000 living has fallen from 160 in 1916 to 99 in 1926, the corresponding rates for the pulmonary form alone being respectively 107 and 69. At first sight it appears to be significant that the period of most rapid improvement in this respect coincides with that of increased effort specifically directed against the disease, in the form of comprehensive anti-tuberculosis schemes. The direct influence of such schemes has been questioned by statisticians, who have no difficulty in demonstrating that the tuberculosis mortality had begun to fall long before sanatoriums were erected or tuberculosis officers came on the scene, and the facts, as they accumulate, certainly give us reason to pause. BROWNLEE'S well-known work on the local variations in the age-distribution of the deaths from tuberculosis indicated that some forces not consciously directed by man were the controlling factors, and BIRAUD'S recent investigations of international records[2] strengthen this suspicion. It is, perhaps, significant that while some towns in England of comparatively recent growth, with sanitation and amenities rather above the average, show an unfavourable trend in the relative mortality from tuberculosis, the position

[1] H.M. Stationery Office. Cmd. 2881. Pp. 379. 6s. 6d. post free 7s.

[2] Preliminary Report on the Causes of the Recent Decline of Tuberculosis Mortality. By Yves M. Viraud, M.D., Health Organisation, League of Nations. C.H. 291. 1925.

in Glasgow, a city which underwent its maximum rate of growth and immigration in the years succeeding the industrial revolution, is improving rapidly. It is justifiable to infer that the mortality from tuberculosis falls, and the force of its blows are felt at later ages, among those especially who have become inured to industrialism and town life. Unfortunately, as the report of the Scottish Board of Health shows, the statistical evidence is not easy to interpret in Scotland, for the very towns in which we should expect these national influences to be most powerful are also those which have carried on the most vigorous campaign against the disease; the organisers of these specific measures may reasonably claim that their influence has been far from negligible. Certain tenets, at least, which had become almost axiomatic in relation to tuberculosis, seem, in the light of Scottish experience, to be open to doubt. Evil housing conditions, overcrowding, and financial insecurity have been blamed for much of the excessive tuberculosis mortality in towns, and yet we find the latter falling at an accelerated rate during a period when industry has been passing through one of the gravest crises in Scottish history, and house-building, as the report shows, has barely kept pace with the increase of population.

Allied to the question of tuberculosis is the system of control of the production and handling of food, and especially of milk, to which an important section of the report is devoted. It is evident that in their efforts to obtain the appointment of whole-time veterinary inspectors, the Scottish Board have been more successful than the English Ministry. There can be no doubt that the effective operation of the Tuberculosis Order and the Milk and Dairies Acts of the two countries must depend largely on the number and efficiency of the whole-time veterinary inspectors appointed to exercise their powers. There is a notable contrast, too, in the policy of the two central departments as regards the control generally of the milk trade. In Scotland the Board, while exercising vigorous supervision over local authorities, has issued orders dealing only with certain aspects of milk inspection, the rest being covered by local by-laws. Licences for the production and sale of all grades of milk are issued by local authorities in Scotland. In England and Wales, on the other hand, the Ministry have withdrawn entirely the power of councils to make by-laws, and have retained in their own hands the licensing of producers of the higher grades of milk. It remains to be seen which policy will lead to more rapid progress and sounder administration, but it seems likely that local authorities and their officers will take greater interest in the operation of their own by-laws than in that of regulations imposed upon them from above.

The incidence and fatality of the epidemic diseases have usually been higher in Scotland than in the southern parts of this island, and it is perhaps, therefore, no matter for surprise that medical officers in that country should have been quicker to apply the modern methods of immunisation against diphtheria and scarlet fever which have been evolved in America. An important experiment at Aberdeen in combined immunisation against scarlet fever and diphtheria by means of one course of inoculations deserves careful attention, as it is obvious that the chance of such prophylactic measures finding acceptance with the public must be seriously diminished in proportion to the frequency with which they require to be applied. The hospital problem has continued to be a subject of active concern. It is gratifying to learn not only that the voluntary hospitals have emerged successfully from their period of financial stress, but also that the central department is not disposed to rest content with a position of stabilised solvency so long as the grave shortage of beds remains. Reference is made to the report of the Hospital Services (Scotland) Committee of January, 1926, known as the "Mackenzie Report," which arrived at the conclusion that Scotland required 3600 beds for general hospital work (including maternity and sick children) and recommended that, while 3000 beds should be found, if possible, by voluntary effort, 600 might with advantage be provided by local authorities for children and women in childbirth. The report further advocated transference of the Poor-law hospitals to local health authorities, and coöperation with the voluntary hospitals in their management. These recommendations are already bearing fruit. Thus, in Falkirk and Stirling, where new voluntary hospitals are projected, the local authorities are proposing to finance the construction and management of maternity wings. Still more interesting is the experiment on foot in Aberdeen where the Council have taken over a detached Poor-law hospital, and are proceeding to manage it in coöperation with the university and the voluntary hospitals.

Generally, the report of the Scottish Board of Health reflects the characteristically energetic and practical manner in which public health administration is conducted in that country. The health departments are obviously concentrating on the solution of problems which have been a reproach to the people ever since the public health conscience was aroused. While the burden must fall most heavily on the local authorities and their officers, much of the credit for the success of their efforts and for their progressive outlook is undoubtedly due to the able and far-seeing guidance of Sir LESLIE MACKENZIE and the medical staff of the Scottish Board of Health.

SMOKE ABATEMENT.

THE Public Health (Smoke Abatement) Act of 1926 came into force on July 1st, too late to enable urban folk to see the eclipse, although the familiar depression "west of Iceland" effectually clouded the sky for most of the country without the help of chimneys. The Act is not the thorough-going reform which the most progressive public health workers would have liked, but it tightens up the law in a number of useful ways. "Smoke," for instance, will in future include soot, ash, grit, and gritty particles for various purposes of the Public Health Act of 1875; and smoke emitted from a chimney (not being the chimney of a private dwelling-house) will be a nuisance for the purposes of Sections 91 and 94 and other parts of that Act, even though it is not black smoke. Penalties under the Act are increased, the maximum being raised from £5 to £50, and the Alkali, &c., Works Regulation Act of 1906 is extended. Two of the most important of the new provisions are the power to prescribe standards in respect of smoke emission and the power to make by-laws respecting cooking and heating arrangements in new buildings. Local authorities have already been feeling their way towards the prescribing of standards; this practice will now be put upon a legal basis. The Ministry of Health intimates that by-laws as to standards should be made in every considerable industrial district. It may not be feasible as yet to apply standards to other than black smoke, but it

will be possible to adopt the form of by-law (of which certain districts have already made trial) which provides that it shall be presumed a nuisance if black smoke is emitted for two minutes in the aggregate within any continuous period of 30 minutes. In London the county council, and elsewhere the borough or urban district council, will now have the right to require such arrangements to be made in new buildings as to prevent or reduce the emission of smoke in the course of heating or cooking. But the expression "new buildings" in this connexion, though it will include clubs and hotels, expressly excludes the private dwelling-house which is responsible for a large share of the polluted atmosphere of our cities. The Ministry, in a sort of apology for allowing the private dwelling-house to escape, has pointed out that both local authorities and private builders nowadays instal methods which tend to reduce the smoke nuisance; it suggests that all possible opportunities should be taken to impress upon householders that the needless emission of smoke can be diminished, but it does not explain how this object is to be attained. Lectures and advertisements, it seems, must supply the place of penal clauses. The new Act has a general exemption for all sea-going ships, and it extends (subject to cancellation by Provisional Order) the old exemption for mines and specified metal processes, so that that exemption will now cover the processes of reheating, annealing, hardening, forging, converting and carburising iron and other metals. Another new and probably troublesome loophole is the statutory defence (on proceedings for sending forth smoke, other than black smoke, from a chimney in such quantity as to be a nuisance) whereby the defendant will be allowed to escape if he shows he has used "the best practicable means for preventing the nuisance, having regard to the cost and to local conditions and circumstances."

The London County Council in its annual report provides some new material for consideration. For several years the Council have kept up observations for the Advisory Committee on Atmospheric Pollution. These observations have been extended in directions more immediately bearing upon health, the results of which are presented for the first time in the report of the medical officer of health for the County of London, which is summarised on another page. The *flèche* of the County Hall has made an excellent view-point for measuring horizontal visibility, and observations are continuous for week-days since September, 1923. The actinic power of the light has been measured by the number of seconds taken to turn a standard paper to a given tint. The method of measuring atmospheric impurities by the collection of the deposits of rain-gauges is only an index of impurities in the atmosphere at times immediately preceding rainfall. For this reason the automatic filter records made by Dr. J. S. OWENS'S instrument, which measures the dirtiness of the air by the shade of blackness imparted to standard filtering paper on filtering definite volumes of air through it, were included in the observations. The three years' records gave the following results: During the summer months (June to August) horizontal visibility was 5·6 miles; during the spring months (March to May), 2·5 miles; during the autumn months (September to November), 2·6 miles; and during the winter months 0·9 miles. During the summer months the light took 17 seconds to turn the standard paper; during the spring months, 36 seconds; during the autumn months, 38 seconds; and during the winter, 63 seconds. The blackening of Dr. OWENS'S filter paper for the summer months was 0·6; for the spring months, 1·0; for the autumn months, 1·1; and for the winter months, 1·4. The monthly variations for each of the three sets of observations are shown in tables and graphs. The shape of the areas of visibility is shown by means of maps with concentric circles a mile apart. In these maps bulges of extended visibility occur in one direction or another, generally towards the quarter from which the wind is blowing. Put in another way, the average area of visibility in London at noon is about 50 times greater in the summer than in the winter and about five times greater in the summer than in the spring and autumn. Further the actinic power of the light is three times greater in the summer than in the winter and twice as great in summer as in spring and autumn. Lastly the amount of dust and tar in the air is three times greater in the winter than in the summer and nearly twice as much in the spring and autumn as it is in the summer. On these findings Dr. MENZIES makes the following comment: "While these seasonal changes in visibility and actinicity are due largely to natural conditions lying wholly outside of human control, there can be no question that coal smoke, which is the main factor in the varying seasonal changes in the filter tint, is an important and aggravating factor in the screening of actinic light, and in intensifying the obscuration arising from the seasonal atmospheric changes to which London is subject by reason of its situation in the valley of a large river."

The value of the new Act will depend, as is so often the case, upon its local administration. Regional committees can study a common smoke problem; local authorities can form joint committees for the discharge of smoke abatement duties, and can also (singly or in combination) undertake investigations and research into atmospheric pollution and its possible remedies. It is desirable that the officers of local authorities should take advantage of special courses of training, and it may be found possible for specially trained officers to help groups of local authorities. The new Act directs that officers duly authorised by the local authority to act in that behalf must, if they consider that a smoke nuisance exists, notify the occupier of the premises forthwith and confirm the notification in writing within 24 hours. This provision is intended to facilitate coöperation between the local authority and the industrial interests within its district. It is a step in the right direction. Not much can be hoped from the Act unless such coöperation can be established.

UNIVERSITY OF LONDON.—The purchase of the Bloomsbury site by the University from the Duke of Bedford was completed on June 24th. The site, including roads, comprises about 11½ acres bounded by Montague-place, Malet-street, Gordon-square, Woburn-square, Upper Montague-street, and Russell-square, and is the site originally bought by the Government for the University and sold back to the Duke in April of last year. The purchase price is £525,000. Of this sum £400,000 has been provided by the donation from the Rockefeller Foundation and £125,000 is derived from a special Government grant in respect of improved accommodation for the University.

BIRMINGHAM HOSPITAL SATURDAY FUND.—Another "record" has been established by this Fund, the total receipts amounting to £53,025 19*s.* 11*d.*, thus beating the previous highest total of £52,287 last year. This is the more remarkable as in view of the industrial troubles of the past year it was feared that the Fund would suffer. The hospitals council has been giving a great deal of consideration to the formulation of the contributory scheme, already referred to in our columns, which is making satisfactory progress.

Annotations.

"Ne quid nimis."

OPTICIAN AND OPHTHALMIC SURGEON.

Two months ago we made some allusion in a leading article[1] to the problems before the Departmental Committee which was sitting to consider the Optical Practitioners (Registration) Bill. This Bill has now been refused a second reading in the House of Commons. The Departmental Committee, however, is still sitting, and is expected to report on the whole subject. The Committee will have before it a memorandum from the President of the General Medical Council, which was approved at the recent session of the Council and may be read in an appendix to its minutes. The attitude of the Council is unchanged from that which it has always maintained. They regard it "as most undesirable in the interests of the public and highly dangerous to the community that persons who have not had a complete medical education should be authorised by law to deal with matters which require knowledge which is pathological or medical, or both." The document then goes on to justify this view by quotations from a statement made at the President's request by Mr. H. L. Eason. "We are prepared to admit," he says, "that where no doubt can exist that the defect is merely an error of refraction, the task of prescribing the requisite glasses should not be beyond the skill of an optician who has undergone the course of training and passed the examination required by certain of the opticians' organisations." He goes on to point out two main considerations which tell strongly against the view that opticians should be officially recognised as qualified to prescribe glasses.

The first point is that in no instance is it possible to certify that the case is one of simple error of refraction without an ophthalmoscopic examination. The second is that it would be unwise for the State to grant recognition to a body of persons who make their living by a special method of treatment and by the sale of special apparatus. In our opinion, the General Medical Council are doing well in attempting to focus the attention of the authorities and of the public on these two points. The prescribing opticians, it is true, claim that those to whom they propose to grant certificates will be well qualified to detect any abnormality visible with the ophthalmoscope, and those who take the trouble to refer to their journal —the *Optician*—will find frequent references to the high standard of training which is now offered to opticians at their "refraction hospitals." To this the answer we would make is that this is not enough. The eye is only a part of the body. To undertake the diagnosis and treatment of its abnormalities and diseases a complete medical training, as well as a special training in ophthalmology, is essential, and it is to the advantage of the public that this should be understood. Take the apparently simple case of prescribing glasses for presbyopes. It need not be questioned that, so far as the immediate requirements of the middle-aged patient goes, opticians can satisfy them in the majority of cases. On the other hand, it must be remembered that there are certain conditions, more or less common in those past middle age, which the ophthalmic surgeon or physician is capable of recognising, and which the trained optician is not. One is incipient chronic glaucoma. Another is abnormalities in the retinal vessels which may point to the necessity of examination of the blood pressure or of the urine. A third is minute retinal hæmorrhages, which may be an indication of septic poisoning arising from some organ far distant from the eye. A fourth is slight lenticular opacities which may or may not be progressive. Frequently they are not.

[1] THE LANCET, April 23rd, p. 880.

In reply to this it may be said, and the *Optician* is very fond of saying it, that the average general practitioner is profoundly ignorant of the eye. In so far as this is true the practitioner is aware of his ignorance, and does not profess anything else. Moreover, this by no means applies to all general practitioners, some of whom possess sound ophthalmic training. The number of those eye specialists and doctors possessing special ophthalmic experience who are now on the "ophthalmic panel" for Great Britain amounts at present to over 800, and if the demand for this special service is sufficient there is no reason why the number should not be increased. Mr. Eason's second point is said by the *Optician* to be a new one, but in fact it has frequently been pointed out before. It is simply that those who prescribe glasses ought not themselves to have a direct interest in their sale. How often have we not seen young people with normal refraction wearing +0·5 D. sphericals purchased from an optician? It is the fashion to laugh at the busy practitioner who supplies his ordinary patients with a bottle of medicine. The unfortunate young clerks and typists who have paid an optician £1 or so for +0·5 D. in fashionable frames would probably have done better to have gone to their panel doctor, for what in many cases they need is a holiday. If the prescribing optician succeeds in his endeavour to monopolise the administration of "ophthalmic benefit," we shall find—it can indeed hardly be otherwise—an increasing number of young men and women wearing glasses for their work without really requiring them. It is this danger to the public which is emphasised in the memorandum of the General Medical Council. The Council's objection is based on principles which apply not only to opticians, but to any class of tradesmen or practitioners who make their living by a special method of treatment.

THE HUNTERIAN MUSEUM.

IN his annual report on the Museum of the Royal College of Surgeons, which has just been issued, Sir Arthur Keith, the conservator of the Museum, mentions that the new specimens added during the year will be on view in Room I. from Thursday, July 7th, until Saturday, July 23rd. Among the additions are many specimens of more than ordinary interest such as a myoma malignum of the uterus —a tumour which, microscopically, has all the characters of a simple myoma, but invades the blood-vessels after the manner of a malignant growth; Paget's disease of the nipple in a stage anterior to the development of a definite carcinomatous tumour; a dissected specimen of bilateral congenital dislocation of the shoulder in an adult; and a large aneurysm of the middle cerebral artery from a case of stenosis of the isthmus aortæ. There is also an interesting group of specimens of thoracic neoplasms, including fibroma, fibromyoma and endothelioma of the pleura, primary carcinoma of the lung, teratomata of the mediastinum, and specimens showing the later results of gunshot injury of the lung. The series of Special Pathology is now being re-catalogued and rearranged, and the Curator proposes to take the opportunity to make the collection more complete as regards the commoner lesions of the body. The value of the Museum for reference in the case of rarer lesions is well recognised, but a large number of students use it as a teaching museum, and donations of examples of the more common lesions would be welcomed; a list of specimens required is available for those who are willing to interest themselves in this matter. The report of Mr. R. H. Burne, F.R.S., the physiological curator, contains a reference to his investigations on the lymphatic system of fishes; he has made the interesting observation that there exists a system of vessels which pour their lymph into the peripheral network of lymphatic spaces, this being drained by lymph vessels of the ordinary sort; the lymph system, therefore, like the blood system, possesses both arteries and veins. During

the year the Conservator has been actively engaged in reporting on many discoveries of human remains, which in several instances have been added to the collection. Among the more important discoveries on which he has reported are the following: for the British Museum, a collection of skulls from Ur of the Chaldees; for the Torquay Natural History Society, a human skull found near the entrance of Kent's Cavern; and for the British School of Archæology in Jerusalem, a report on the Galilee skull. Much progress appears to have been made in the preparation of the catalogue of the collection of human skeletons, one of the largest departments in the Museum; in this work the Conservator has for some years had the assistance of Miss M. L. Tildesley, who contributes a separate report on the progress of the work. As we announced at the time,[1] the greatly extended odontological room was formally opened on May 23rd by the President, Sir Berkeley Moynihan, in the presence of the members of the Odontological Section of the Royal Society of Medicine, who, with the Zoological Society, have recently made numerous valuable donations to the collection. The whole collection has been rearranged by the honorary curator, Sir Frank Colyer, and is now much more accessible for the purposes of study. Appended to the annual report is a list of publications connected with the Museum, the results mainly of research which is actively promoted there. The number of visitors and students who used the Museum during the year was 7578; the requests from teachers of ambulance and science classes for permission to visit the Museum on Saturday afternoons, accompanied by their pupils, continues to increase, the yearly total of students attending on these occasions amounting to over 3500.

A SYRINGE FOR BLOOD TRANSFUSION.

TRANSFUSION of blood is now so frequently and generally employed that any simplification of technique is to be welcomed. In our present issue (p. 22) Dr. R. R. Macintosh describes an apparatus which seems to combine simplicity with efficiency. The only difficulty that we can foresee is that the later part of the blood drawn into so large a syringe might not be well enough mixed with the citrate solution to prevent partial clotting. The formation of even a very small clot would result in blocking of the nozzle. Probably this is avoided by using an excess of citrate, such as is contained in 2 drachms of a saturated solution. The necessity for this would be regarded by some as an objection to the method, but the apparatus will commend itself to those who are not influenced by that consideration. For medical uses the syringe should prove particularly useful, as it is more common in medical practice to give frequent transfusions of relatively small amounts of blood.

MEDICINE ON A MODERN LINER.

THOSE who go down to the sea in ships can do so with increasing confidence that if they should need medical attention they will get it. Now that the large Transatlantic and other steamship companies have begun to offer their medical officers adequate pay, a sufficient staff, and first-class equipment for the care of the sick, their passengers can rely on the service of cautious and capable surgeons, no less brilliant, although perhaps less erratic, than the traditional ship's doctor. At the invitation of the Canadian Pacific Railway our representative visited last week the refitted *Empress of Australia*, a vessel of 21,850 tons displacement, 615 feet long, with a beam of 75 feet, oil-fired engines of 10,000 h.p., and a sea speed of 18 knots, running up to over 20 at a recent trial. The vessel possesses all the luxuries of the sea, attractively decorated saloons, writing-rooms, lounges, a gymnasium, and a swimming bath, as well as nurseries, and very comfortable cabins for both first- and third-class passengers. The whole ship is ventilated by fresh air supply, and every cabin and other space is heated by electric radiators. The medical equipment leaves little to desire. The medical officer has a large and attractive cabin, next to which is a waiting-room for patients, and beyond that the operating-room. Here are seen the first-class passengers and hither are transported all requiring surgical treatment from other parts of the ship, crew or passengers, who are first seen in the dispensary, which is forward, and on the deck below. The operating-room is well equipped with table, sinks, sterilisers, lights, and instrument cupboards, also an incubator, and good work can and has been done here. Below is a hospital for the third-class passengers and for the crew, six beds in two tiers for men, each of whom is allowed an iron locker for his effects; a bed-pan locker, bath, w.c., filter (Chamberland pattern), a fan, and an electric heater, as well as a mess place. Outside is a cabin for the two hospital attendants, and in the passage is a telephone by which the doctor can be quickly found wherever he is. On the adjacent female side there are also six beds with equally satisfactory equipment, and another, curtained off and wider, for a labour case. Our representative found the infectious section the best he has seen. Set up upon a large poop, completely cut off from the people of the ship, it has a nominal capacity of 14 beds, but these can be increased. They are in five sections, women to port, men to starboard. There is no suggestion of skimping about this place, or of makeshift, but the baths (fresh water, hot, cold, and shower) and the water-closets are just as good as elsewhere in the ship or better. Fans, radiators, filter, telephone, fire extinguisher, everything is complete, a steam disinfector not forgotten. The infectious diseases most apt to cause trouble are measles, chicken-pox, and diphtheria, but luckily they rarely all appear together. Dr. Gardner, the staff surgeon, finds no difficulty in carrying out the necessary microscopical work on board. The cabin accommodation is, for all classes, very good, an electric bath and radiant light bath give comfort to travellers with rheumatism on their way to healing springs. There is a laundry which can wash 5000 pieces of linen a day; but this ship burning oil makes less demand than most on the linen we carry with us. Cooking is done with coal, baking by electric mixers and electric ovens. There is a steam dish washer, a travelling grating carries the dirty cup or plate into a chamber where fierce, fine jets of steam clean it thoroughly, and it is delivered dry and shining to be put away. The rotary plate cleaner in the first-class pantry takes into little boxes the plate, soap, and a myriad of tiny soft lead balls (like shot but not hardened with antimony); this mixture being heated and revolved together the plate comes out clean and polished.

The accommodation for the crew is distinctly good, though bunks are still arranged along the ship's side, a danger in case of collision. There are many mess places and all are good. The dressers or sideboards are all of metal, probably steel, galvanised; this is to diminish insect infestation. Each man has a steel locker for his clothes, and cubic space probably in excess of standard. The washing basins of the men, as we had occasion to note in another ship recently, are not made with good enamel, consequently they will never look clean. When there are hot water supplies all over the ship elsewhere, it seems wrong that hot water should not be supplied for the crew, who certainly need it. A great advance is that there is a man whose duty it is to keep these annexes in order. The company provides holders, too, for latrine paper rolls, but does not seem to provide the rolls, judging by the litter of torn newspaper over the floor. The recent improvement in these places in ships is surprising; 15 years ago it would have seemed hopeless to expect a seaman to have a self-flushing closet, with plentiful headroom, no difficult corners to clean, daylight, forced ventilation, a basin and a fresh-water tap alongside him. Wonderful have been

[1] THE LANCET, May 28th, p. 1142.

the changes since Dr. Collingridge's paper appeared in our columns on May 5th, 1894.

Apart from the medical arrangements with which we are primarily concerned, there was mention of new navigational aids, wireless direction-finders, giving a position within a degree, and a hydraulic gauge to tell the bridge what the draught of the ship is without going over the side to learn it. There was also talk of Atlantic Park, a hostel at Eastleigh, where the company assembles and cares for its transmigrants from Europe to Canada. Everything is thought out, everything is planned for their comfort, in the hope they will come again. The ship and her crew appear worthy to represent the British Merchant Marine in carrying, on her next trip, the Prince of Wales and the Prime Minister to the Overseas Dominion.

THE DANGER OF IRRADIATING MILK.

AN editorial article in the *Journal of the American Medical Association* for May 7th points out the danger of rashly irradiating foods in order to increase their content of vitamin A. The danger is a real one and is of particular importance where milk is concerned. It is true that the antirachitic value of milk can be significantly improved by exposing it, in the liquid or dry state, to the action of ultra-violet light, and rickets has been cured in children by the administration of such directly irradiated milk. As a vehicle for the administration of vitamin D, irradiated milk might in certain cases find a use, but as a complete food for infants its employment is undesirable. Apart from the unpleasant taste which irradiation imparts to the milk, there is no security that certain of the vitamins which it contains may not have been destroyed. As long ago as 1919, S. S. Zilva [1] investigated the action of ultra-violet light on the vitamins A, B, and C. The two last he found were little if at all damaged, but vitamin A in butter, for instance, was completely destroyed under the conditions of the experiment, owing to formation of ozone by the ultra-violet light waves. Conditions might be so arranged commercially that the destruction of vitamin D did not take place, but many safeguards and tests would first be necessary before the product could be safely used. Meanwhile direct irradiation of the cow or feeding her with cod-liver oil seem safer methods to use, for at any rate the milk is not thereby, as far as we know, robbed of anything nor is it rendered unpalatable. The case is different in regard to older members of the community, who consume a mixed diet in which the vitamin A is obtained from a variety of different sources; in countries with long sunless periods, for example, there might be scope for some one irradiated article of diet to supplement the vitamin D in the ordinary dietary.

ORTHOPÆDIC SOFTENING OF BONES.

IN the May number of the *Jahrbuch für Kinderheilkunde* Dr. Carl Rabl describes a method of softening children's bones before correcting their deformity by orthopædic measures. The softening is produced by local and general acidosis; local acidosis is promoted by the application of a rubber bandage so as to cause congestion of the limb, whilst general acidosis is obtained by giving ammonium chloride by the mouth. In 8 to 18 days, it is stated, the bones are so soft that they can be bent and the deformity corrected. In metabolic experiments it has been shown that if marked acidosis is produced a considerable loss of calcium occurs after the second or third day. The calcium must be drawn from the bones, as other organs contain relatively little and are slow to part with it, and it is on this fact that the method depends. The most intense local acidosis is obtained when administration of ammonium chloride is combined with energetic local congestion. The detail of the technique needs close attention and this form of treatment is still in the experimental stage. The greatest difficulty is to obtain the right degree of compression; the limb must become slightly cyanosed (blue-red) but must remain warm, and the bandage is applied for about 20 hours daily. The dose of ammon. chlor. is 0·2 g. per kg. of body-weight per day. It is given twice daily in 4 per cent. solution in syrup. Larger doses have been given by other workers, but Dr. Rabl thinks them risky. During the period of softening, all antirachitic foods are carefully avoided and the child is protected from sunlight, though complete darkness is unnecessary. The correction of the deformity is carried out under narcosis and is not always easy, the bones being so elastic that it is necessary to over correct and put up the limb in plaster. The tendency to recurrence remains for a long time and it is only after three weeks that the splints can be removed for a few hours at a time. Antirachitic treatment is started energetically immediately after operation. No investigations indicating the degree of acidosis produced by Dr. Rabl are reported, but it is stated that no serious symptoms occur and that recovery is rapid. The most suitable cases for treatment are children under 2 years old. In Dr. Rabl's opinion the softening of the bones associated with acidosis is not identical with the softening of true rickets or osteoporosis, and he discusses their relationship.

AN OPPORTUNITY FOR PHARMACISTS.

THE last quarter of a century has witnessed fundamental changes in methods of diagnosis and treatment. These changes are reflected in the radical alterations in the training of medical students which, in contrast with the system that was practised in the days of our grandfathers, is now based upon a new science. The application of physiology, X rays, blood counts, bacteriological tests; salvarsan, insulin, throat swabs, pituitary extract, sera, and vaccines—all these are things that belong to a newer school. It is, we think, common ground that pharmacy, which has been called the handman of medicine, has not kept pace in the march of medical progress. Great improvements have been introduced into the pharmaceutical curriculum, and the present-day pharmacist receives a better technical training than was usual even 10 or 20 years ago, but it is admitted that the educational scheme in the case of pharmacy has not undergone a major operation of anything like such a drastic character as that to which medical training has been subjected. The division of a qualifying examination into two parts, and the requirement of evidence that a student has been educated rather than coached, are all to the good, but they cannot be styled as far-reaching. According to Dr. J. H. Burn, director of the Pharmaceutical Society's Pharmacological Laboratory, the pharmacist "remains content to busy himself with the dispensing of those remedies which are for the most part rapidly ceasing to be regarded as of serious medical value, and it is urgent that he should realise that by doing so he is continually lessening his national importance." The occasion on which this was said was the sixty-fourth annual meeting of the British Pharmaceutical Conference, which was held at Brighton last week, and the context is a paper in which Dr. Burn endeavoured to show the need for adaptation to changed conditions. The Pharmacopœia, he says, is notoriously out of date, yet it has been allowed to control the pharmacist's training. We are not quite so certain as Dr. Burn that the time has come to scrap the Pharmacopœia or that the new science has advanced far enough to replace it. But that is not the point with which we wish to deal. Dr. Burn's object, we take it, was to demonstrate the desirability of adapting pharmaceutical training to medical progress. He says, in effect, if a patient goes to a medical consultant he will find that very often the consultant forms his opinion of the patient's condition as a result of several examinations he makes or arranges to have made: X ray examination, blood examination, and a bacteriological

examination. Here, he thinks, is work for the pharmacist, yet there is nothing, or very little, in the pharmacist's training to fit him to do this work.

To remedy the deficiency courses should be instituted so that students could be thoroughly trained in such processes as sterility tests, the preparation of vaccines, the examination of throat swabs, and so on. There is no doubt much to be said in support of Dr. Burn's ideals, but the average pharmacist may think them too lofty for practical purposes. Perhaps the most cogent argument in his favour was the one used by the secretary to the Pharmaceutical Society who, in the course of the discussion which followed the reading of the paper, said it was the function of the pharmacist to provide any medicinal agent which might be required by a medical practitioner. We are not in the secrets of the pharmaceutical authorities, but it seems significant that both the Society's secretary and one of its chief scientific officers should show by public utterances that they are in favour of providing means to equip pharmacists for this new work. Unfortunately, the idealists will find very little active support and no enthusiasm in the rank and file. We say this on the evidence of a pharmacist who is in close touch with members of his calling. The small, very small, band of pharmacists who have fitted themselves for work of the kind which Dr. Burn has in mind have had very little encouragement to go on with it. Some of them have found work to do, but when they were just getting into their swing a county council or some other public body has relieved them of their task, and, indeed, the general tendency in this matter seems to be towards centralisation. The subject is not a new one; we discussed it in these columns some two years ago, and can now see no reason to alter the conclusion we then reached that at some future time we shall probably see two classes of pharmacist—the one class with lip sticks as a "side line," to use an expression familiar to the confraternity, and the other composed of the poor but faithful sons of Galen.

THE STEPHEN PAGET MEMORIAL LECTURE.

Stephen Paget was associated so closely with the activities of the Research Defence Society that a lectureship endowed in his name is a fitting memorial. The first Stephen Paget memorial lecture was given on June 21st by Mr. Julian S. Huxley, until recently professor of zoology in the University of London. Mr. Huxley has recently relinquished his chair in order to devote all his time to the interpretation of scientific facts and advances to the general public, and he has started his new career well in expounding at the outset the value of research to the community. The scope of his lecture included a review of the relations of animals and plants to their environment and of the dangers of introducing either to new countries without careful consideration of the possible consequences. The upset of the balance maintained by the normal checks to multiplication and spread of any species in its natural setting might be followed by disastrous results. On the other hand, efforts to exterminate animals or plants that were found to do damage must be undertaken only after careful study of their prey or habits of growth, since some other worse pest might become manifest without their restricting influence. The economics of the transport and acclimatisation in different countries of medicinal or edible plants were discussed in even greater detail recently by Dr. A. W. Hill in a lecture given at the Royal Institution. Both lecturers made it clear that agricultural research is a paying proposition for any nation, and even the most conservative and dogmatic of "practical farmers" benefits indirectly from the modern work on heredity and parasitology which he still affects to despise. A more delicate matter is the need to convince the public that experiment as well as observation is required for the progress of medical science. Prof. Huxley cited examples of benefits to mankind and to animals that had resulted from experiment, recalling the testimony of Pasteur and Lister and quoting modern instances such as insulin. Finally he pointed out the relation of experiments on animals to the control of animal diseases such as rabies, anthrax, and glanders. The Research Defence Society should not be looked on as a body merely organised to resist attack on the essential methods of medical research, but as a body prepared to fight actively against ignorance and apathy.

ETHYLENE AND CARBON MONOXIDE.

TOXIC symptoms following the inhalation of ethylene at the St. Francis Hospital, Pittsburg, led to an inquiry into the chemistry of the gas, from which some conclusions have been drawn which are of much practical import. It has become obvious that unless special care is taken in the production and in the storing in cylinders of ethylene there is risk of contamination with carbon monoxide. The symptoms of poisoning alluded to above were in fact attributable to carbon monoxide, and at least one fatality due to this poison has followed the inhalation of ethylene. The manufacturers of the ethylene used offered every facility for the inquiry, and the result of this work should be a uniformly high standard of ethylene production in America. So far as we are aware, there has as yet been no reason to suspect the purity of any of the ethylene made for anæsthetic purposes in Great Britain. The use of the gas here has of course been on a very much smaller scale than in the United States, and indeed it does not so far appear from the literature and from experience that there is any large number of cases in which ethylene can give results superior to those obtainable from nitrous oxide, oxygen, and ether, properly employed. Considering also the unpleasantness of its odour, and the elaborate precautions recommended for abolishing all risks of explosion, we find it hard to become enthusiastic for the frequent employment of ethylene.

GOOD AND BAD MATING.

NEARLY at the end of his life Francis Galton wrote: "When the desired fullness of information shall have been acquired, then and not till then will be the fit moment to proclaim a 'Jehad' or Holy War against customs and prejudices that impair the moral qualities of our race." Such is the sane pronouncement of the founder whose followers have sometimes been less discreet in their enthusiasm. He saw at any rate that nothing could be done in a hurry, and that the aim of human eugenics was something beyond fleshly perfection. Whether he would be satisfied with the progress which has been made in acquiring the necessary information we do not know; in many ways little seems to have been accomplished, but Galton probably realised that the unravelling of human inheritance would be no trivial business. He would surely have been pleased with the moving appeal which the Galton professor delivered to London school teachers in November last,[1] an audience which perhaps sees the good and evil results of human matings more nakedly displayed than do most people. He urged upon them that enough was now known to justify practical action in some cases and to convince everyone who would look at the facts that eugenics is a really serious matter which needs their close attention. More particularly he desired them to cultivate the frame of mind which looks upon the production of a bad child, or a child which may be bad, as a thing which is not done; the mating of a woman of a hæmophilic family is racial incest and should be abhorred as is family incest. Prof. Karl Pearson points his argument with the familiar family trees of defects—claw hand, hæmophilia, mental deficiency, cataract—and repeats his gloomy prophecy that if man evades the selective action of natural selection and does not replace it by reasoned conduct he is bound to deteriorate. We doubt

[1] The Right of the Unborn Child. Eugenics Lecture Series XIV. By Karl Pearson, F.R.S. Cambridge University Press. 3s.

whether the fullness of our information justifies this argument; in the moral and spiritual levels on to which human evolution is progressing, natural selection may be rather more difficult to understand than the crude form with which we are familiar. And we are glad to see that at the last annual meeting of the National Tuberculosis Association at Indianapolis, U.S.A., Prof. H. S. Jennings, of Johns Hopkins, read a paper on the thesis that health progress is quite compatible with race progress, and that campaigns against tuberculosis, infantile mortality, cancer, and so on are in no sense dysgenic or even anti-eugenic. His argument, broadly speaking, is that there is no evidence that the lives which are saved by intensive health work are, on a proper scale of human values, undesirable lives. But whether Prof. Pearson is right or wrong in this, he does one thing in his excellent discourse which eugenists (including Prof. Jennings) too often forget. He does not merely horrify his audience with pedigrees of undesirable people, but with family trees of the Bernoullis, the Bachs, the Walpoles, and such like; he shows that good mating produces good results just as bad mating produces bad results. We know, more or less, how mathematics or music or statesmanship can be encouraged just as well as we know how hæmophilia or mental deficiency can be diminished. And we are sure that eugenics will make a stronger appeal to people at large in this positive aspect; a general conviction that bad breeding is not done must have its counterpart in a belief that good breeding is worth while.

THE TRADE DISPUTES BILL.

APPREHENSION exists that the Trade Disputes and Trade Unions Bill may prove so widely drafted as to cover any controversy in which the medical profession is engaged—for example, if it is making a united stand in protest against the conditions of some general or particular service demanded of it. It is worth while to insist that the Bill should be so worded as to remove any doubt, though possibly the apprehension is unfounded. The point arises in two passages in the Bill. Clause 1 declares a strike illegal if it has any other object than the furtherance of a trade dispute within the particular trade or industry, or if it is designed or calculated to coerce the Government. "Trade or industry," it has been suggested, might cover action by the medical profession. The second passage is in Clause 8, which defines "strike" to include the cessation of work by a body of persons employed in any trade or industry, or a concerted refusal or a refusal under a common understanding of any number of persons so employed. The Bill, however, limits the meaning of "trade dispute within a trade or industry" to disputes between employers and workmen or between workmen and workmen—words which occur in Section 5 of the Trade Disputes Act of 1906. No court is likely to say that "workman" includes medical practitioner. The word "business," which the Bill does not use, has often been defined as including a profession—for instance, in the Partnership Act, the Business Names Registration Act, and various taxing enactments. But the word "trade," when defined in the Income Tax Act, certainly excludes professions. It will be remembered that the Finance Act of 1925 had to make special provision to concede to the profits of a profession the deduction for wear and tear which had always been allowed in the case of the profits of a trade. The Income Tax Act speaks of "trade or profession," "trade, profession, employment or vocation," in a manner which shows trade and profession to be distinct. Trade in the technical expression "offensive trade" has been held not to include the carrying on of a lunatic asylum. On the other hand, the legal rules about "restraint of trade" (covenants not to carry on business within a certain radius) have been applied to the covenants of doctors and dentists. "Industry" is defined in the Unemployment Insurance Act in terms which have no reference to a profession. On the whole, therefore, it does not appear that the medical profession is in danger, though its antagonists will doubtless wish the Bill to apply.

Another passage in the Bill deserves notice. Clause 6 proposes that any person employed by a local or other public authority who wilfully breaks his contract of service with that authority, knowing or having reasonable cause to believe that the probable consequence of his so doing (either alone or in combination with others) will be to hinder or prevent the discharge of the authority's functions, shall be liable to fine or imprisonment on summary conviction. There is here no limitation to trade or industry and no exclusion of professional services. The Bill is now before the House of Lords, where further clarification may be found possible.

THE annual election of members of the Council will take place at the Royal College of Surgeons of England on July 7th. Fellows who have not already voted are reminded that votes must be received by the Secretary not later than 10.30 A.M. on that day. There will be a reception at the College from 3.30 to 5 P.M. on the same day, and at 5 P.M. the Lister Memorial Lecture will be delivered by Prof. A. F. von Eiselsberg, the Lister Medallist for 1927.

Messrs. Hempson have drawn our attention to a mistake in the preface of the book entitled "The Conduct of Medical Practice," recently published by us. The firm of Hempsons, which is composed of Mr. W. E. Hempson, Mr. O. A. Hempson, and Mr. C. M. Oliver, holds the appointment of solicitors to the Medical Defence Union, but the appointment of solicitor to the British Medical Association is held by Mr. W. E. Hempson personally, and not by Mr. O. A. Hempson and Mr. C. M. Oliver, as was erroneously stated in the preface. We express our sincere regret for this unfortunate mistake.

INDEX TO "THE LANCET," VOL. I., 1927.

THE Index and Title-page to Vol. I., 1927, which was completed with the issue of June 25th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Tuesday, July 5th, at 2 P.M., Dr. Barty King will give a special demonstration at the Royal Chest Hospital; on the same date Dr. Dan McKenzie will demonstrate at the Central London Throat, Nose and Ear Hospital at 2.30 P.M. On Friday, July 8th, at 5 P.M., Mr. M. L. Hine will give a lecture-demonstration on iritis and cyclitis at the Royal Westminster Ophthalmic Hospital. All of these demonstrations are free to members of the medical profession. The Prince of Wales's General Hospital, N.-E. London Post-Graduate College, Tottenham, will undertake a vacation course from July 11th for two weeks. The course, which is an all-day one, 10.30 A.M. to 5.30 P.M., will include instruction in general medicine, surgery, and the specialties. The lectures at 4.30 P.M. are open to members of the Fellowship. Special visits will be made on the two Saturdays to the North-Eastern Fever Hospital and to the L.C.C. Mental Hospital, New Southgate. St. Mark's Hospital will give a special course for one week beginning July 11th, occupying six afternoons and three mornings, and including operations, lectures, X ray and pathological demonstrations. Two other courses taking place in July are part-time courses—one in neurology at the West End Hospital for Nervous Diseases from July 4th to 30th, and consisting of lecture-demonstrations at 5 P.M. daily; the other, a course in infectious fevers, at the Park Hospital, S.E., on Wednesdays, at 2.30 P.M., and on Saturdays, at 11 A.M., from July 13th to 30th. A general course of work is also provided at the associated hospitals, for which a comprehensive ticket is issued and a separate programme published. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Fellowship of Medicine, 1, Wimpole-street, W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXX.

MALIGNANT DISEASE OF THE UTERUS.*

I. General Considerations.

WOMEN suffering from cancer of the uterus can be permanently cured if the growth is discovered sufficiently soon. Early diagnosis, therefore, is the first and most important step in the treatment of the disease, and of latter years considerable efforts have been made to secure this by disseminating amongst the laity knowledge of the symptoms that are its first outward sign. The result of these efforts is, I think, a definite tendency amongst women to go to the doctor earlier than they did, but one still sees many cases in which the growth has attained to an advanced stage before the sufferer seeks medical advice, and others in which the early signs of the growth have been overlooked or misinterpreted by the medical man, occasionally from lack of care, but more often because the early symptoms did not conform to text-book teaching.

Danger of Inverted Symptoms.

The constant symptoms of cancer of the uterus are bleeding, discharge, and pain, and this is the order of incidence in most cases. Intermenstrual bleeding at any age, but particularly in women over 35 years, demands prompt attention and investigation, and still more does bleeding coming on after the menopause. This is now generally understood. It is not so generally appreciated, however, that the order of incidence of the main symptoms may be altered, so that discharge may precede bleeding, or pain both bleeding and discharge. These atypical cases make up the bulk of those in which the seriousness of the condition remains unsuspected until it is too late to cure the patient.

The idea that carcinoma of the uterus is invariably accompanied by bleeding is by no means correct. Such absence of bleeding is most often met with when the cancer is corporeal, and especially when the uterus is senile, for then the cervical canal may be very narrow or even obliterated. The growth silently eats its way through the uterine wall, and the first patent intimation of its presence is sudden ascitic enlargement of the abdomen, secondary to metastatic growths in the peritoneum. If, however, the history of these unfortunate patients be investigated, it will be found that they have long been conscious of vague pain low down in the abdomen. Cancer of the cervix, though less commonly, may also run an entirely or almost bloodless course. Such growths may spread far into the paracervical and paravaginal tissue before anyone is aware of their presence. The process of infiltration is, however, accompanied by pain, the origin of which is mistakenly attributed to colitis, or if complained of down the leg to neuritis, the latter diagnosis having a certain amount of truth in it, as the pain is due to the obturator nerves becoming involved with the infiltrated glands. Even when bleeding is the primary sign of uterine cancer, it may only occur at long intervals, and then very scantily. This particularly applies to corporeal disease.

Difficult Physical Signs.

It is evident from the foregoing how important it is to examine vaginally a patient presenting vague lower abdominal or pelvic symptoms. But even after the vaginal examination is made the diagnosis may not be clear. This is particularly true of carcinoma of the corpus, in which vaginal examination may reveal nothing, not even bleeding. With carcinoma of the cervix, too, the physical signs may be equivocal. Thus endocervical growths, until they have broken through the vagina, present no ulcerating or fungating surface, whilst some ectocervical growths are very difficult to distinguish from an erosion, especially when the growth starts at some point on a pre-existent erosion, as it very frequently does. In all such difficulties the proper course is to examine the woman under an anæsthetic and remove a portion of the suspected tissue, dilating the cervix, if necessary, to do this. It cannot be too frequently emphasised that "the change" is not normally accompanied by continuous or irregularly repeated bleeding. True, such bleeding often occurs at "the change," but this is because uterine disease or degeneration is so common at that epoch. In spite of much propaganda, women as a whole cling to the dangerous delusion that irregular bleeding is normal at the menopause, for compared with the deep ingraining of old wives' tales modern hygienic education is a mere veneer.

Cure of Cancer of the Cervix.

Turning now to the curative treatment of cancer of the cervix, it is certain that the disease if discovered sufficiently early can be permanently cured by suitable operative measures. This leads us to a consideration of what is meant by "sufficiently early." The question is easily answered from the strictly histological aspect—namely, that the operative cure of carcinoma implies the excision of the primary growth, together with an area of tissue that comprises every lymphatic channel and gland infected by cells derived from the primary growth, and that if the extent of the growth permits such an excision, the patient is cured. From the clinical standpoint, however, an answer cannot be given with such definiteness, for we have no means of exactly ascertaining the extent to which detached carcinoma cells have permeated the surrounding tissues, though we can often be fairly certain which structures the primary growth has or has not infiltrated.

When is a Growth Removable?

The task set the clinician is to decide whether or not the growth is removable, or at least whether the chances of its being removable are worth embarking on an operation to remove it, and this decision must be based both on the results of his physical examination and on a consideration of the symptoms complained of by the patient, both being equally important.

It is necessary to remember the directions in which the growth may spread—namely, downwards, backwards, forwards, and sideways.

Extension rarely takes place by *upward spread*. Even in patients dead of the disease, the corpus is usually pretty intact. The result is that enlargement of the body of the uterus is usually conspicuously absent, and when it does occur, it is usually due to a pre-existent fibroid or to distension of the uterus with pent-up pus (pyometra). The first cause gives rise to no pain, but the second to both pain and fever. Enlargement of the uterus from either of these causes is, however, no bar to an operation.

Downward spread carries the growth into the vaginal walls, and this in itself does not prohibit an operation which removes most of the vagina, so long as the growth has not passed from the vaginal wall to the structures underneath it. In general, the further down the vaginal wall the growth has spread the greater the chance that the structures deep to it are involved. For instance, a growth half-way down the anterior wall has nearly always involved the bladder base, though on the posterior wall more extension is allowable before it is probable that the rectum is involved, for the upper inch of this wall is separated from the bowel by Douglas's pouch. Mistakes in estimating the extent of the downward spread of the growth are frequently made owing to the fact that its advancing edge often forms a projecting ridge like a ring round the vagina, and this is taken to be the lower border of an excavated cervix, whereas it is nothing of the sort. It is important in examining these cases to measure the distance of this edge from the vaginal outlet, for if the distance is less than that of the normal vaginal wall the growth has involved the vagina.

Extension down the lateral walls is accompanied by an increasing risk of involvement of the ureters. Actual cancerous infiltration of the ureters occurs late. At first they are merely pushed outwards; later on the growth may surround them either entirely or partially, so that they run in a deep groove. Sooner or later they become obstructed, not, as might be thought, by the actual growth

* An article on Malignant Disease of the Uterus, II., Operative Measures and Irradiation, will appear next week.

of cancer taking place in their substance, but from contraction of the cancerous growth outside them, so that they become constricted about an inch above their junction with the bladder. Following such constriction, the ureter dilates above the obstruction, and so does the pelvis of the kidney. That this dilatation is not due to growth in the ureteral wall is proved by the fact that if the ureter be dissected out of the growth the dilatation immediately subsides.

Gross extension directly outwards from the cervix, besides involving the ureters, sooner or later reaches the pelvic side wall, forming a buttress-like mass which more or less fixes the cervix; this massive infiltration of the paracervical tissues gives rise to pain of an aching character felt deep down in the abdomen and in the groin. But besides this method of extension, there is going on in this direction another, far more insidious—namely, lymphatic permeation—by which cancer cells may reach the same goal without the formation of any mass that can be felt, and without any pain. The principal route of lymphatic permeation in cancer of the cervix is, in fact, directly outwards into the glands in the obturator fossa, which may be extensively involved, causing pain, felt down the front and inner side of the thigh without any tangible paracervical thickening.

Extension of the growth forwards involves the bladder at the junction of its posterior wall and base. The first symptom of this is increased frequency of micturition, coupled with pain in the act. Later on changes appear in the urine, which contains pus or blood, or both.

Extension directly backwards presently reaches the peritoneum on the anterior wall of Douglas's pouch. When this happens, the rectum or a coil of the pelvic colon becomes adherent at the point where the growth is threatening to break into the peritoneal cavity, and this prevents general peritoneal dessemination. Instead a mass is formed, largely in the wall of the infiltrated gut, and intestinal symptoms appear. Thus there is pain in the back and rectum, made worse by defæcation, and later on diarrhœa with, perhaps, blood in the stool. A degree of flatulent distension of the abdomen will be noticed in its lower part.

The reason of this detailed description of the directions in which cervical cancer spreads, and the symptoms associated with the spread, is that the decision whether a growth is probably removable depends upon an understanding of these things.

Important Questions.

In examining any individual case, not only should the size and degree of fixity of the growth, and the length of the vagina under the growth, be ascertained, but two important questions should be asked.

The first is: "Have you any pain?" An answer in the affirmative indicates that in all probability the growth has passed beyond the confines of the cervix into the paracervical tissues or regional glands, for if still limited to the cervix it is not, as a rule, painful, the exception being massive endocervical carcinoma, in which the tissue tension is very excessive.

The second question is: "Have you any trouble with the bladder—difficulty, frequency, or pain?" If the woman replies "None," the probability is that the growth is removable, because by far the commonest absolute bar to the completion of the operation is deep involvement of the bladder. If, in addition, the urine is normal, it is quite certain that the bladder is either not involved or only very superficially so. If, on the contrary, the patient replies that she *has* trouble with the bladder, its duration should be inquired about. For instance, she may say that she has great frequency, but on questioning it may be disclosed that she has had frequency for years. The urinary symptoms due to a carcinoma of the cervix are of short duration. Frequency is less grave than pain, and pain than difficulty, for frequency does not necessarily indicate deep infiltration of the bladder, whereas difficulty almost invariably does. The urine should then be examined. Normal urine implies that the mucosa at least is uninvolved, whereas pus and blood indicate the contrary. When in spite of interrogation and ordinary examination doubt still exists as to the degree to which the bladder is infiltrated, the cystoscope should be employed.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:
POSITION OF THE MEMBERS.

As our readers are aware [1] the direct representation of Members on the Council of the Royal College of Surgeons of England is being investigated afresh by the Council of the College. At the annual meeting of the College held on Nov. 18th, 1926, a resolution was passed to the following effect:—

"That this thirty-eighth meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College and respectfully requests the Council to take a postal vote of Fellows and Members on the general principle as set out in this resolution."

The Council of the College has acceded to this resolution so far as to request a postal vote from the Fellows on the "desirability of direct representation of Members on the Council." This request was circulated to the Fellows with an explanatory statement regarding the claim for representation. A considered reply to this statement has now been issued by the Society of Members, signed by Dr. Ernest E. Ware (President), Dr. Redmond Roche (Vice-President), Mr. J. Lawson Dick (a Fellow and a member of Council), and Mr. Hubert Pinto-Leite (Hon. Secretary). The statement is here reproduced in full, and in the concluding section dealing with the six specific claims made on behalf of members the remarks of the Council are followed in each case by the reply of the Society to them.

EXPLANATORY STATEMENT BY THE COUNCIL OF THE COLLEGE.

Historical Abstract.

The Royal College of Surgeons was incorporated by Charter in 1800. The old Company of Surgeons was declared to have been dissolved, and a new corporation was established. Under the Charter of 1800 the governing body or Court of Assistants, as it was then called, consisted of 21 persons. Eighteen were named and appointed in the Charter, and three were added at the first meeting of the Court. They were appointed for life with power to fill up vacancies as they might happen, and from them were chosen the ten Members of the Court of Examiners, the Master and two Governors or Wardens being selected from these ten. The Charter of 1822 changed the titles of Master and Governors to President and Vice-Presidents, and provided that the Court of Assistants should in future be styled the Council of the College. The Charter of 1843 took away from the Council (increased to 24 Members) the right of self-election, made provision for the abolition of life membership of the Council, and made membership of the Court of Examiners no longer the exclusive privilege of Members of the Council. A new body of Members to be called Fellows was constituted and the election of the Council was placed exclusively in the hands of the Fellows, for Fellows alone were made eligible to vote for and sit upon the Council. The Council were empowered, under certain conditions, to elect to the Fellowship all Members of the College who were such at the time that the Charter of 1843 was granted. Since that date it has been open to all Members to obtain the Fellowship by examination.

From the incorporation of the College in 1800 the Court of Assistants or Council had been composed mainly of surgeons holding hospital appointments, and the Charter of 1843 required that a Member of the Council should not practise midwifery or pharmacy and should be in bona fide practice as a surgeon.

[1] THE LANCET, June 4th, p. 1191.

That restriction remained in force till 1888, but, as provided by the Charter granted in that year, any Fellow of the College who has been a Fellow of the same for ten years or a Member of the same for 20 years, is now eligible as a Member of the Council without any restriction as to mode of practice.

Functions of the College.—The reason for the grant of the Charter of incorporation in 1800 is stated in the following recital:—

"And whereas it is of great consequence to the Commonweal of this Kingdom that the art and science of Surgery should be duly promoted and whereas it appears to Us that the establishment of a College of Surgeons will be expedient for the due promotion and encouragement of the study and practice of the said art and science, Now we etc."

These words, repeated and emphasised in the Charters of 1822 and 1843, have been held to indicate that the functions of the College are twofold—one scientific, concerned with the promotion of the science of surgery, and the other academic and professional, concerned with the promotion and encouragement of the practice of surgery, including the examination of students and others to qualify for practice or honours in surgery and kindred subjects. The College endeavours to promote the science of surgery by means of the museum, the research laboratories, and the workrooms attached to the museum, the library, Hunterian and other lectures, demonstrations, and the award of prizes. The study and practice of surgery are promoted by the regulations drawn up for the education and training of students and the examinations for the several diplomas granted by the College.

Financial Arrangements.—Under the terms of the Agreement made with the Royal College of Physicians of London in 1884 for a Conjoint Examining Board, the Diploma of Member can only be granted in association with the Licence of the Royal College of Physicians, and candidates for the Diploma of Member no longer pay fees directly to the College of Surgeons. A fee of 40 guineas (exclusive of fees, if any, for re-examination) is paid to the Conjoint Examining Board for the two Diplomas of M.R.C.S. Eng. and L.R.C.P. Lond., and after payment of the expenses incurred in conducting the examinations, the remaining balance is divided equally between the two Colleges and paid over to them by the Board. A Fellow, in addition to the fees paid by him through the Conjoint Examining Board, pays a fee of 20 guineas (about to be increased to 30 guineas) for his Diploma of Fellowship, or, if not previously a Member of the College, pays a fee of 30 guineas (about to be increased to 50 guineas). No further payment is made either by a Fellow or a Member.

Rights and Privileges: Members.—1. The right to the description M.R.C.S. and the right to be registered under the Medical Acts of the United Kingdom if the Diploma of Member is held together with the L.R.C.P. Lond. 2. The use of the museum and library. 3. Attendance at all lectures and demonstrations held within the College. 4. Eligibility for professorships and lectureships and for collegiate prizes. 5. Eligibility for the examinership in physiology for the Fellowship, the examinerships in anatomy, physiology, midwifery, and pathology, under the Conjoint Examining Board, and the examinerships for the Diplomas in Public Health, Tropical Medicine and Hygiene, Ophthalmic Medicine and Surgery, Psychological Medicine, and Laryngology and Otology. 6. The right to wear a distinctive gown. 7. Eligibility to attend and vote at the annual meeting of Fellows and Members, and to receive a copy of the annual report of the Council.

Fellows.—The Fellows have the same rights and privileges as the Members, and in addition: 1. The right to vote at the election of Members of the Council. 2. Eligibility for membership of the Council (*a*) if a Fellow of ten years' standing, or (*b*) if a Fellow who has held the membership for 20 years. 3. Eligibility for the Court of Examiners, the examinership in anatomy for the Fellowship, and the Surgical Section of the Board of Examiners in Dental Surgery.

Diplomas and Degrees.—In 1887 the Royal Colleges of Physicians and Surgeons petitioned the Crown for power to grant degrees in Medicine and Surgery to candidates passing the conjoint examinations. The petition failed, as have also two schemes considered from time to time for conjoint examinations with the University of London. Since 1887, however, the University of London has been reconstituted, and several new universities in the provinces and Wales have been founded. Medical students, accordingly, have better opportunities of obtaining degrees in Medicine and Surgery, and at the present time 83 per cent. of those obtaining the Diploma of M.R.C.S. are university students.

Claims of the Members.—Since the institution of the annual meeting of Fellows and Members in 1885, resolutions in favour of giving Members of the College some form of direct representation upon the Council have been brought forward and passed almost every year. On behalf of the Members it has been claimed:—

1. That, as Members of the Corporation, they are entitled to a share in the management and government of the College.
2. That the Council is composed entirely of consulting surgeons and does not represent the Members, most of whom are engaged in general practice.
3. That before 1843 Members of the College were eligible for Membership of the Council, and that the Charter of 1843 made them no longer eligible.
4. That the interests of the Fellows, of whom many are engaged in teaching or as consultants, do not always coincide with those of the general practitioners who constitute the great majority of Members of the College.
5. That a large proportion of the income of the College is derived from fees paid by candidates for the Diploma of Member.
6. That steps should be taken to remove the many disabilities from which, it is stated, Members of the College suffer, as compared with graduates of Provincial, Welsh, and Scottish Universities.

REMARKS ON THESE CLAIMS AND REPLIES OF THE SOCIETY OF MEMBERS.

Claim I.

"That, as Members of the Corporation, they are entitled to a share in the management and government of the College."

Remarks of the Council.—There are some 18,000 Members, many resident in distant parts of the world and many whose names have never been entered on the Medical Register of the United Kingdom, and it would not be practicable to arrange an election of Members of the Council, with membership of the College as the sole qualification for those who vote.

In universities it is generally required that graduates who wish to exercise rights within the university should, after graduation, take steps, including the payment of an additional fee, to have their names placed and retained on the register of their university. It is obvious that some such system would be required if the right of voting were conceded to Members of the College, and it is not known whether Members would be prepared to pay an additional fee and place themselves on an electoral roll of the kind indicated in sufficient numbers to justify the suggested change in the constitution of the College.

The rights of electing Members of the Council and of being eligible for a seat on the Council, hitherto confined to the Fellows, have been acquired by the Fellows after passing a further examination in surgery and paying additional fees. They are among the chief advantages which the College itself confers on the Fellowship, and could not be conceded to others without interference with the principle at present embodied in the Charters that the government and management of the College shall be in the hands of those who have done something more than take a pass degree or diploma and have given some evidence of their intention to devote themselves specially to the practice of surgery.

Comment by the Society of Members.—Apparently it is acknowledged in the preamble that the Members of the Corporation are entitled to share in the manage-

ment and government. In reply to the difficulties raised as to the method of carrying out the election registration, a composite fee, as is done by the London University, might easily be arranged. Moreover, a draft scheme has been submitted to the Council of the College by the Society of Members showing alternative methods. This, after all, is a trivial matter and one capable of easy adjustment. That the taking of the Fellowship is evidence of intention of future devotion to surgery is refuted by the Council's remarks on Claim II., since on the Council's own showing a large majority of Fellows is in general practice. At no time have Members claimed to have a vote for the election of the whole Council, but only for a limited representation by some of their number on that body.

Claim II.

"That the Council is composed entirely of consulting surgeons and does not represent the Members, most of whom are engaged in general practice."

Remarks of the Council.—The Council is elected by the Fellows, a majority of whom are in general practice, and there is nothing to disqualify a Fellow in general practice from becoming a Member of the Council.

The result of an inquiry made a few years ago showed that in the whole of Great Britain and Ireland there were not more than about 400 practitioners entirely engaged in consulting surgical work (general and special), some of these not being Fellows of the Royal College of Surgeons of England. At the present time there are some 1800 Fellows of the College, and it is certain that a large proportion of them is engaged in general practice.

Comment by the Society of Members.—It is true that a Fellow engaged in general practice might be elected to the Council, but with one possible exception, this has never happened. Members, however, seek representation by a few of their own number. To ask that some three Members should be elected to represent the views of 18,000 is not an extravagant claim.

Claim III.

"That before 1843 Members of the College were eligible for Membership of the Council, and that the Charter of 1843 made them no longer eligible."

Remarks of the Council.—Before 1843 a Member could be elected a Member of the Council, but the Council was always composed mainly of surgeons holding hospital appointments or some high official office, and its personnel did not differ essentially from that of councils elected since that date. It was never the right of the general body of Members to elect the governing body. When a vacancy in the Council occurred this was filled by the vote of the existing Members of the Council.

Comment by the Society of Members.—The remarks on this claim betray some evidence of sympathy with an absolute autocracy which was killed by the Charter of 1843. This Charter created Fellows as a higher order of Members but did not deprive Members of their existing privileges. At the present time Fellows derive their legal status to deal with finance from their rights as Members. In proof of this, is the fact, that if a person becomes a Fellow without having previously acquired the Membership, this latter is conferred upon him to legalise his position.

Claim IV.

"That the interests of the Fellows, of whom many are engaged in teaching or as consultants, do not always coincide with those of the general practitioners who constitute the great majority of Members of the College."

Remarks of the Council.—Many Fellows are engaged in general practice, and the interests of the Fellows, so far as it is legitimate for the College to promote them, do not differ from those of the Members.

The College was founded to promote the study and practice of surgery for the benefit of the public. There is nothing in the Charters empowering the College to promote the interests, other than the professional interests, of Fellows and Members. Being only one of several medical licensing authorities, the College could not deal effectively with social and ethical questions affecting not only Fellows and Members of the College, but all members of the medical profession. Such questions pertain rather to some central authority such as the General Medical Council, or some voluntary intraprofessional organisation such as the British Medical Association.

Comment by the Society of Members.—Since the College was founded to promote the study and practice of surgery for the benefit of the public, and the public is largely attended by general practitioners, of whom very many are Members of the College, it follows that the needs of the public are best appreciated by the Members of the College. Hence, it is only just to the public that the Members should have some representation on the Council, in order that they may voice the views of the guardians of the public health on educational subjects, and on matters of general professional interest on which, from time to time, the Council is consulted. Mutual coöperation is much needed and this is all that is desired by the Members.

Claim V.

"That a large proportion of the income of the College is derived from fees paid by candidates for the diploma of Member."

Remarks of the Council.—It is true that the share of the fees for the Diplomas of M.R.C.S. Eng. and L.R.C.P. Lond. paid to this College by the Conjoint Examining Board after defraying the expenses incurred in conducting the examinations forms an important part of the income upon which the College is dependent for its existence. The proportion, however, varies greatly from time to time, and so recently as 1921 it was less than the realised surplus from the fees for the Fellowship and the Licence in Dental Surgery.

Comments by the Society of Members.—It is difficult to understand why the Council in estimating the income for 1921 from Fellows and Members respectively, should have added the income derived from candidates for the licentiate in dental surgery to that derived from candidates for the Fellowship. It would seem more reasonable to add the income from the Licentiates to that derived from candidates for the Membership, since many of the Licentiates are already Members of the College.

As a matter of interest, the figures of income from candidates for the Fellowship, Membership, and Licentiateship respectively, for the last two years are as follows:—

1925 .. .. £4496, £26,459, and £5899.
1926 .. .. £4768, £23,239, and £4264.

Thus the claim of the Members that they are the main financial support of the College is fully justified.

Claim VI.

"That steps should be taken to remove the many disabilities from which, it is stated, Members of the College suffer, as compared with graduates of Provincial, Welsh, and Scottish Universities."

Remarks of the Council.—Members of the College acquire the same rights and privileges under the Medical Acts as graduates of universities. It is not possible for the Council to influence the estimation in which the Diploma of Member and a medical degree are respectively held by the public. No doubt there is a special prestige in a university degree, but the Diploma of Member has also a value of a special kind, which is recognised not only in this country, but in foreign countries and the Dominions beyond the seas.

Comment by the Society of Members.—The Members' claim is that the Conjoint Diploma has been proved by professional standards to compare most favourably with many university degrees. In the pass lists for the services, &c., university degrees are set out, but no mention is made of the Conjoint Diploma. Many hospitals require candidates to possess a university degree to the disadvantage of those holding the

aforesaid diploma. We think that effective action on the part of the Council would rectify this and we consider this an instance in which representation of Members on the Council would be of material help. With the concession to Members of limited representation on the Council, the privileges and influence of the Fellows would remain unimpaired while the Council would be brought into harmonious relations with the large body of Members on whose loyal support it is greatly to the interest of the College to be able to rely.

The reply of the Society of Members which has also been circulated to all the Fellows concludes with the expression of a hope that the result of the polling will end a long and vexing controversy which has disturbed the College for 38 years.

MEDICINE AND THE LAW.

Limitations on Unrestricted Publicity of Judicial Proceedings.

THE question how far the unlimited publicity in connexion with deaths under anæsthetics causes needless and harmful panic in the public mind is one of fact not of law. As a matter of law, an examination of the statute-book shows that, while publicity of judicial proceedings is a British tradition, Parliament has always been willing to surrender the tradition in the face of abuses prejudicial to public or private interests. Thus the safety of the realm made it a reasonable precaution to provide that prosecutions under the Official Secrets Acts might be heard in camera. Under the Children Act the court can be cleared when a child gives evidence. To prevent injury to public morals the publication of reports of judicial proceedings containing indecent matter was prohibited, and the reporting of divorce cases was restricted by a rather imperfectly drafted Act of 1925. Private as well as public interests were presumably protected when the Criminal Justice Act of the same year forbade both the photographing of a judge, juror, litigant, or witness in court or in the precincts of the court, and the publication of such a photograph in the press. Personal interests again were considered when Parliament allowed the doors of the courts to be closed to the public at the hearing of applications under the Adoption of Children Act and the Guardianship of Infants Act. Such examples indicate the statutory limits to publicity in judicial matters. Persons are not to be exposed to prejudice or blackmail merely to preserve the citizen's right to read about their domestic affairs in his daily newspaper. And, outside the sphere of judicial proceedings, there are other statutory limits. Voting by secret ballot is a limitation of publicity which everyone accepts. Post-office officials must not disclose the contents of telegrams, nor must income-tax officials fail to observe secrecy. Publicity has a relative, not an absolute, value.

In so far as the jurisdiction of the coroner is affected by the proposal to limit publicity in connexion with the deaths of patients to whom anæsthetics have been administered, it must be remembered that a coroner's court is not necessarily open to all the world. Exactly a hundred years ago Lord Tenterden delivered a judgment which laid down that a coroner's court was, like any other court of justice, open to the public so long as space was available and provided that there were no special reasons to the contrary. If there are special reasons to the contrary—the interests of justice or decency, for instance—the coroner has a discretion to exclude the public or any particular persons. The suggestion has been made from time to time that deaths occurring in hospitals should be investigated by tribunals selected from panels of medical practitioners of known reputation and approved qualifications and experience. It should not be impossible to devise some such tribunal which would be acceptable to the Home Office and which would be recognised as adequate by the public. And it should be possible to allow the representation of all parties at the inquiries held by such a tribunal without permitting unlimited publicity and exaggerated sensationalism in the reports of its proceedings.

Alleged Negligence of Dental Hospital.

An important ruling on the duty of a dentist, where a tooth goes down a patient's throat, was given by Mr. Justice McCardie in the case of Cooper *v.* Mirron and Sinclair, in which Mrs. Cooper claimed damages for the death of her daughter, aged 30, alleged to be caused by the negligence of the defendants in the extraction of her teeth at the National Dental Hospital, Great Portland-street. The learned judge, in summing up to the jury, observed that it was clear that Miss Cooper died as a result of septic trouble due to a piece of tooth having gone down her windpipe. One of the issues of the case, he said, was whether her life could have been saved if proper steps had been taken in time; the medical evidence on the whole seemed to show that it might, and it was open to the jury to take that view. Several times during the examination of the witnesses Mr. Justice McCardie questioned them as to what teaching is given to dental students in the matter of the steps to be taken if a tooth enters a patient's windpipe. Dr. Arthur Underwood, sub-dean of the National Dental Hospital, and lecturer and examiner in dentistry, gave detailed evidence on this point which other witnesses had left a little vague. The judge told the jury that, where a tooth went down the throat of a patient, whether the symptoms of distress were serious or not, the dentist's duty was clear. He must tell the patient what had happened, and must take steps, by X rays, to locate the foreign body and to have it removed if it were in a place of danger to the patient. Those were the things which should be done whether the dentist practised in the country or in town. In the case then being tried, said the judge, everyone in the operating-room knew that the tooth had gone down the patient's throat. It was now known that, if a tooth went down the throat, it might go down the airway and serious consequences might result. It was for the jury to say whether the defendants (or either of them) were guilty of negligence in not informing Miss Cooper or her friends of what had taken place, and in not taking steps to ascertain where the piece of broken tooth actually was. The special jury returned a verdict for the plaintiff against the defendant, Mr. Gabriel Mirron, with damages £150; they took the view that death had resulted from his negligence. They added that they considered from the evidence that the general committee of management of the National Dental Hospital was deserving of very severe censure, and that it was possible that the case against Mr. Mirron would not have been so severe if there had been a tighter hold on the management by the committee and officials. Asked by the judge what was the ground for censuring the hospital committee, the foreman referred to the absence of care as to who was present at the operation. By this he appeared to mean that a stricter record should have been kept of the persons actually present. This seems a trifling matter by comparison with the issue of negligence; but the evidence had disclosed questions of responsibility at the operation, and doubt as to the actual presence of the medical superintendent of the hospital, Dr. Alfred Sinclair, one of the defendants. The reasoning processes of the collective mind of a jury (even if it is a special jury) are matters of uncertainty and speculation. An external unanimity is often attained by compromise. The verdict of this jury, which took some time to reach a decision, possibly meant that several of its members thought that the plaintiff ought to have some remedy, and that the hospital as an organisation, rather than any particular defendant, was to blame. The hospital, however, was not sued; it will be matter for argument whether the verdict against Mr. Mirron can be upheld. Judgment has been reserved, pending an application by counsel on either side.

THE HEALTH OF LONDON IN 1926.

Dr. F. N. Kay Menzies presents his first complete annual report[1] as medical officer of health for the County of London, which forms Chapter I. of Vol. III. of the annual report of the County Council. The Registrar-General estimates the 1926 midyear population at 4,605,400 civilians and 10,000 non-civilians. This estimate allows for an increase of 91,400 since the census, and as the excess of births over deaths during these five years was 165,500, emigrants must have exceeded immigrants by about 74,000 persons.

Housing.

A table shows that the City and the 28 metropolitan boroughs, which make up the county, erected 4252 houses for the working classes, made 57 closing orders, and demolished 110 houses, while 316 houses were demolished voluntarily—a net addition of 3769 houses. The chapter on housing shows that, in addition, 4643 houses and flats were erected by the County Council with accommodation for 34,650 persons. One infers that as the annual increase in population is under 20,000, some progress was made in 1926 to make up for war arrears, although the table in Dr. Menzies's report shows that only 589 of 1640 cases of overcrowding were remedied by the boroughs, and a footnote states that in many cases it was impossible to take effective action for overcrowding owing to the shortage of houses.

Birth- and Death-rates.

The births in the county numbered 78,825, making a birth-rate of 17·1. The death-rate from all causes was 11·6; from tubercle, 1·03; from cancer, 1·46; and from pneumonia, bronchitis, and influenza combined, 1·9. The infant mortality-rate was 64, and the rate from diarrhœa and enteritis under 2 years per 1000 births was 12·0. The table giving the vital statistics in the metropolitan boroughs shows, of course, considerable variations. The following are some of them, leaving out of count the peculiar small population of the City to be dealt with elsewhere. The three boroughs with the highest birth-rates were: Shoreditch (23·3), Poplar (21·6), and Bethnal Green (20·9); and those with the lowest were Westminster (11·3), Hampstead (12·3), and Holborn (12·4).

The lowest death-rates from all causes were recorded in Lewisham (10·1), Woolwich (10·2), Wandsworth (10·6), and Hampstead (10·6); whilst the highest occurred in St. Marylebone (13·0), Southwark (13·0), and Finsbury (12·9).

The lowest infant mortality-rates were in Lewisham (43), Woolwich (43), and Stoke Newington (49); and the highest in Holborn (90), Paddington (86), and St. Marylebone (85). The lowest rates for diarrhœa, &c., under 2 years were in Lewisham (4·9), Woolwich (5·3), and Hampstead (5·6); whilst the highest were Paddington (25·2), Holborn (22·4), and Stepney (18·6). The lowest rates for phthisis were recorded in Hampstead (0·58), Holborn (0·60), and Paddington (0·70); and the highest in Shoreditch (1·28), Finsbury (1·15), and Bermondsey (1·15).

Tubercle.

Dr. Menzies discusses the variations of the phthisis mortality. He points out that when the mortality from phthisis is stated as a percentage of deaths from all causes at each age-period much of the difference between the various boroughs disappears, and that the simplest and most obvious measure of the health of the population, especially the adult population, is afforded by the death-rate from all causes. He quotes with approval Osler's dictum that nutrition is the chief factor. In the case of children or persons under 20 years of age the highly urbanised environment of London does not appear to involve a high mortality from phthisis, but it is suggested that the explanation of the high London mortality is to be sought in the effect of population movements. Young adults of both sexes emigrate from London north of the Thames. Young immigrants, on the other hand, being unaccustomed to the London environment possibly fare worse than the native-born population. It is also suggested that emigrants do not take with them relatives, who are accommodated in London institutions. An illustration of this may be found in the fact that the lunatic asylum population of London is proportionately twice as great as that of the country as a whole. Dr. Menzies draws attention to the increase of phthisis among young women during recent years. This increase has been greater in London than in the aggregates of the urban and of the rural districts of England and Wales, and began to operate before the war (and possibly as far back as the 'nineties), and it is suggested that it may be associated with the taking up by women of business pursuits. After the age of 25, when more of the women are married, there is little evidence of this increased incidence of mortality through phthisis.

The Council have promoted a scheme for the trial of artificial light treatment for tuberculosis, and ten of the borough councils decided during the year to avail themselves of the facilities provided at certain hospitals and centres. The employment of tuberculous persons has received attention. Twenty-five ex-Service men, who had been trained at the Godalming Sanatorium, are being employed in the manufacture of leather goods at the Spero workshop, Hatton-garden, and 20 ex-Service pensioners are being employed at the Spero firewood factory, King's Cross. Selected patients have been employed in the Council's parks as gardeners, and it is found that the value of their work is about three-quarters of that of an ordinary park labourer. The number employed is to be increased from 4 to 12, but selection will be limited in future to employees of the Council. The boarding-out in clean healthy homes in the country of children from homes heavily infected with tuberculosis was begun in April, 1925, and up to the end of 1926 324 such children were successfully boarded out. Facilities for the residential treatment of tuberculosis have been increased. The M.A.B. have opened a hospital at Grove Park, Lee, with accommodation for 151 men and 171 women, chiefly for advanced cases, but 11 male beds and 12 female beds are reserved for surgical cases. The institutions used by the Council for advanced cases are not entirely reserved for this type. The improved facilities for the prompt treatment of children are shown by the fact that there is now no waiting-list either for pulmonary or surgical cases.

Small-pox.

Two small outbreaks of small-pox, comprising five and two cases respectively, affected London, and in both the infection was derived from Paris. Only five of the cases with one death from the confluent type actually occurred in London; the other two cases with one death from the hæmorrhagic type occurred in Willesden. It is remarkable that up to now London has not been invaded by the mild type of the disease prevalent in the midlands, northern counties, and South Wales. The expert medical staff is available for the home counties in aiding the diagnosis of suspected cases.

Diphtheria, Diarrhœa, Anthrax.

As to diphtheria, the case mortality of this disease has decreased greatly since the introduction of antitoxin in 1894. Thus the percentage figures for the eight 4-year periods beginning with 1895–98 has been 17·8, 12·2, 9·2, 8·7, 7·0, 7·4, 7·4, ending with 4·7 for the period 1923–26.

In June, 1923, Dr. Foord Caiger, of the M.A.B., addressed a letter to the medical press deploring the fact that such a high percentage of cases of diphtheria were admitted to hospital in a moribund state in view of the almost invariably successful results obtained by the early administration of antitoxin. Many metropolitan boroughs keep a supply of antitoxin at the town hall, and Dr. Menzies suggests that other

[1] From P. S. King and Sons, Limited, Westminster. 2*s*. 6*d*.

public places might be used as accessory sources of supply of antitoxin in order to make it readily accessible for all parts of each borough. A comparison of the various districts shows that the diphtheria death-rate is much higher below 2 years of age in the poorer boroughs, whereas in the more well-to-do boroughs a slightly higher mortality is found between the ages of 5 to 15. An unusual outbreak of diarrhœal disease occurred in Poplar in the second week in July. Samples of water in the affected area gave very unfavourable results when examined bacteriologically. It is thought that the outbreak may have been caused by polluted water from the gasworks being forced into one of the mains. There were seven cases of anthrax notified, five attributed to foreign hides and one to feathers from China. The one fatal case was a baby aged 1 year living in Paddington. The diagnosis was confirmed bacterially, but the origin of the disease could not be traced.

Encephalitis Lethargica.

There were 173 confirmed notifications of encephalitis lethargica with 68 deaths. During the years 1919 to 1925 there were 1325 true cases notified with a 37 per cent. mortality. A study of these cases shows: (1) that the incidence is highest at the 10 to 20 age-period, and especially at the period from 15 to 20; (2) that there is a slightly higher incidence among boys from 0 to 15 years, although the fatality was slightly higher among girls at these ages; and (3) that the case fatality is greatest under 5 years and over 35 years. The London cases were over four times as many as the Sheffield cases which formed the material of the Medical Research Council's Report (No. 108). The London experience confirmed that of Sheffield in that no relation could be traced between the disease and a poor or insanitary environment and water- milk- or food-supply. In London the susceptibility of young males was less marked and most noticeable at the age of puberty, and not at the time of sexual maturity as in Sheffield. In both experiences it is agreed that statistical estimates of the incidence and fatality of the disease are vitiated by the occurrence of unrecognised, mild, and abortive cases. Dr. Menzies estimates that in London the unnotified cases exceed the notified by 50 per cent. The accommodation of 100 beds at Winchmore Hill is quite inadequate to deal with the after-effects of the disease, and is only a clearing house for juvenile cases. More accommodation is needed for the careful and patient investigation which up to now has thrown no light on causation or effective preventive control.

Some other Causes of Morbidity.

According to the periodicity rule given in the last report an epidemic of influenza should occur in April, 1928, with its maximum about the thirteenth week of the year. When allowance is made for the change in the age constitution of the population between 1911 and 1921 it is found that the female deaths from cancer have actually decreased in number, while the male deaths have shown only a slight increase during that period. There were 90 deaths among the 337 notified cases of puerperal fever. In addition, the Registrar-General recorded 30 deaths from puerperal sepsis which were not notified. This gives a death-rate per 1000 births of 1·5. Midwives summoned medical aid in 17·5 per cent. of the 40,000 confinements attended by them, about the same percentage as last year. Of the 413 cases of ophthalmia neonatorum occurring in the practice of midwives there was impairment of vision in one eye in two cases, whilst in three the result could not be ascertained owing to removal. Fifty-seven cases were admitted to St. Margaret's Hospital. Several outbreaks of pemphigus neonatorum in the practice of midwives caused anxiety. The cases numbered 140, and the disease took a mild form.

Bacteriological Work.

The laboratory examined 11,121 specimens. The work included a full inquiry as to the milk-supply of Claybury Mental Hospital, and a comparison of the water of two swimming baths supplied with a special plant of the Turnover Filter Co., and of two swimming baths with untreated water, the result being entirely in favour of the specially treated water. A large amount of useful work was also done in the differential diagnosis of various nervous complaints.

The condition of the River Lee continued to be unsatisfactory. After heavy rains in July the Navigation Cut from Tottenham Lock downwards was especially bad, masses of putrifying débris being churned up by passing barges. This stream is still used by the rowing clubs of East London. The state of the Wandle is improved as the result of a better effluent from the Wandle Drainage Board. Many examinations of the water of open-air swimming baths were made. In one of the South London parks a paddling pond was cleaned and refilled with water from the mains. Within a fortnight the water was bright red, and microscopical examination showed an abundant growth of a red protococcus. For an early record of a similar occurrence Dr. Menzies refers us to Exodus VII. In the present instance a small dose of sulphate of copper successfully killed the organism which did not reappear.

NATIONAL PHYSICAL LABORATORY.

A RECEPTION AT TEDDINGTON.

THE annual inspection of the National Physical Laboratory at Teddington, on June 24th, was attended by more than 1000 visitors, who were received by Sir Ernest Rutherford, President of the Royal Society and Chairman of the Board, Sir Richard Glazebrook, Chairman of the Executive Committee, and Sir Joseph Petavel. To the medical visitor the majority of the exhibits were of spectacular rather than personal interest, but there were a number of demonstrations on the borderland of medicine and physics.

Protection against X and Gamma Rays.

The vital problem of protection against the X rays and the still more penetrating gamma rays of radium was made the subject of a comprehensive exhibit, showing the method of testing a variety of protective substances. The relative efficiency of building or other materials is expressed in terms of the "lead equivalent," the ratio being determined by direct comparison between pure lead and the material under consideration. The absorption of the rays due to a known thickness of the material—concrete, for example—is measured by means of an ionisation electroscope, and the thickness of pure lead which will absorb the rays to the same extent is found by experiment. The thickness of lead equivalent in absorbing power to unit thickness of the material is the "lead equivalent." The advantage of knowing the protective efficiency of building materials used in the construction of X ray departments is obvious, and it seems unfortunate that adequate protection is not compulsory in the construction of all such buildings.

Light and Colour.

The optical department contained some interesting apparatus for the measurement of colour. The equipment is designed to determine the properties of the "normal" human eye as judged from measurements of spectral colours by a large number of observers. When this determination is completed it will form a connecting link between the various practical methods of colorimetry and the physical properties of colouring materials. The study of colour blindness has always been hampered by the difficulty of establishing a standard of normal vision, and any advance in the direction of expressing colour vision in terms of wave-length rather than in terms of coloured beads or wool is to be welcomed. Spectrophotometry is of increasing importance in medicine as the only reliable method of testing glasses and filters for use in actinotherapy. A wide range of

glasses of known transparency or opacity to different regions of the ultra-violet spectrum is now available, and no doubt such glasses will find a place in modern "sunlight" clinics. Much of the apparatus now in use has been designed and constructed at Teddington, and embodies the most accurate methods of spectrum analysis.

Glare.

The efficiency of vision in the face of glare is being studied from the point of view of street lighting. The eye is very inefficient at detecting inconspicuous objects when a beam of strong light is falling on the retina, and it frequently occurs that motorists are at the greatest visual disadvantage when passing the headlights of an oncoming car. It is expected that, as a result of experimental study, it will be possible to design motor headlights of an efficient but less dazzling type than those commonly used at present.

The usual interest was shown in the testing of clinical thermometers, of which some 600,000 pass through the laboratory during the year. The test is exacting, and, although not compulsory, it is evident that most clinicians prefer to have the official stamp on their thermometers.

The exhibits in general showed a wide application to the needs of science and industry.

BRITISH HOSPITALS ASSOCIATION.

SEVENTEENTH ANNUAL CONFERENCE AT NORWICH.

THE annual conference of the British Hospitals Association was held in the Blackfriars Hall, Norwich, on June 23rd and 24th. Sir ARTHUR STANLEY, the President, was in the chair.

After the Lord Mayor (Mr. C. R. BIGNOLD) had welcomed the delegates the President delivered his address. He said that during the past few years a change had been taking place in the hospital world. Sooner or later the voluntary hospitals would be obliged to reconsider their position in regard to the general social welfare of the population. From their original function, as mere dispensers of charity, they had gradually become centres of training and research. But in their progress they had been content to maintain a state of isolation with no organised coöperation between them and the State and public authorities. Now the State's conception of its duty in regard to public health service had changed and had assumed a policy of initiative and aggression. In consequence the voluntary hospital must also change its position.

Relationship between Voluntary Hospital and the State.

What were the desirable relationships which should exist between the voluntary hospitals and public authorities? To answer this question the President quoted from a letter written by the Secretary to the Minister of Health, dated Feb. 15th, 1927, giving a list of suggestions to be examined by them in conjunction with local authorities, including boards of guardians. Amongst these was the possibility of taking stock of local health needs and coming to some agreement as to the lines of demarcation between the voluntary and the public hospitals in the area; of making a category of cases to decide the advisability of drafting the patients either to a voluntary or to a public hospital; of making some arrangement on "clearing house" lines; and of ascertaining to what extent the medical staffs of the voluntary hospitals would undertake responsibility for cases, or for a certain number of beds in public hospitals.

As to State aid, the voluntary hospitals had long opposed this form of help on the ground that it would be the forerunner of State control. But there were signs that gradually the State was drawing the voluntary hospitals into a public medical service. The hospitals received payment for work in connexion with venereal disease, maternity and child welfare, antenatal clinics, tuberculosis, &c. Whether these payments come from the State or from the municipal authorities, the principle was the same. In this way, little by little, the voluntary hospitals were becoming part of a State scheme without the more spectacular Treasury grant. It was most important that the voluntary hospitals should take a very broad view of the situation. They should develop more and more as the real centres of medical life in the area in which they were situated, all clinics and treatments under the public health service being associated with them. If the voluntary hospital were regarded as the consultative centre the Poor-law infirmaries would act as municipal hospitals, not only receiving incurable and chronic cases, but also taking in all simple medical and surgical cases which the domestic circumstances of the patient might render unsuitable for treatment at home. With such a coördinated scheme the patient would come to realise that his condition was the deciding factor as to where he should be nursed, and the voluntary hospital, relieved of all its trivial cases, would be able to devote its energies, accommodation, and funds to special work, for which it was admirably fitted. In conclusion, said the President, the voluntary hospitals are fast arriving at the parting of the ways, and they cannot hope to take their proper place in the prevention of disease unless they accept the undoubted advantages of a coördinated scheme of public medical service.

Discussion.

Colonel D. J. MACKINTOSH (Glasgow) said that they were quite alive to the fact that when the Poor-law hospitals were taken over by the public health authorities it was bound to affect the voluntary hospitals. But this need not necessarily be in an adverse way.

Colonel VERNON (Bournemouth) considered that the great stumbling-block which the Minister of Health would be likely to encounter in amalgamating the medical work of the country was the medical profession. He did not think that a medical man should be asked to undertake work for the State in a voluntary capacity. Young men who gave service to the hospital and were desirous later of specialising should, he thought, be given some assistance by the voluntary hospital. This ought not to be difficult, as voluntary hospitals were becoming more and more paying institutions, with paying patients and contributory schemes.

Mr. A. N. CROUCH (Somersetshire) had come to the conclusion that the hospitals could not do more than they were doing at present. There was considerable enthusiasm in the work and the result of interference would be to check the work and reduce voluntary effort.

Mr. HUTTON (Gloucester Royal Infirmary) said he feared that if any of the functions of a voluntary hospital were handed over to a public authority the cost of administration would at once go up. Speaking for his own hospital, the members of the working men's contributory scheme would, he was sure, be most antagonistic to any junction of their functions with those of a public body.

Mr. EDWIN PEARCE (Stockport) agreed that the time had come when an honorarium should be given to the so-called honorary medical staff of a voluntary hospital.

Mr. H. T. LOVE (Government Inspector of Charities in Victoria, Australia) said that they had in Australia the voluntary hospital system with State aid. But this did not connote interference, and the system worked well. He warned all present never to have their hospitals nationalised as in New Zealand, for the costs had run up to an astonishing degree.

Mr. BRIGHT (Royal Victoria Hospital, Bournemouth) expressed the hope that meetings would be organised in big centres to discuss these questions before the hospitals were forced into the unfortunate position of accepting anything the State might give them.

Motor Accident Cases in Hospitals.

The afternoon session was given up to a discussion on Motor Accident Cases in Hospital from the Insurance Point of View. The first speaker was Mr. N. J. JENKINS, a vice-president of the Council of the Insurance Institute of London. He said that the company he represented insured many thousands of motor-cars, and the policy usually issued included medical expenses within certain limits. Therefore if the hospitals were out of pocket very considerably by reason of motor accidents in the streets it would seem that the Hospitals Association should introduce some machinery to deal effectively with the position. But as long as the underlying principle of the administration of the hospitals was a voluntary one it was difficult to see how a payment for maintenance or services rendered could be enforced. Moreover, the insurance contract, as it at present stood, was between the insurance company and its policy-holder, and the hospital authorities could have no lien on the sums payable under the policies. If hospitals were legally entitled to intercept payment made by insurance companies it was easy to foresee that the hospital charges would increase enormously. The doctors, surgeons, anæsthetists, and so forth, who now freely gave their services, would rightly claim payment. It might be true that some persons injured by motor-cars had not the means to pay towards their hospital treatment, but statistics proved that in this respect the motorist was most impartial; rich and poor were treated alike. The moral sense of the casualty patients must be quickened, and when they plead inability there seemed no reason why the hospitals should not offer to accept payment by instalments. Instead of the Hospitals Association endeavouring to obtain statutory powers to intercept payments made by insurance companies—in Mr. Jenkins's opinion an entirely futile hope—he suggested that application should be made to the Government for a grant from the Road Fund. By his recent action the Chancellor of the Exchequer had admitted that this fund was not sacrosanct.

Mr. G. Q. ROBERTS (St. Thomas's Hospital) considered that an extra 10*s.* on to the insurance policy for institutional treatment would help the hospitals materially; he thought they ought to ask Mr. Jenkins to bring that matter before the insurance companies.

Mr. BLANCHARD (Sheffield) said that it seemed when an insured person was taken to a nursing home and liability proved the insurance company paid the claim. They only repudiated it when the claimant was the voluntary hospital.

Captain GREGG (Lowestoft) said that many hospitals were providing private wards for motor accident cases and were entering into special contracts with their patients. This should put the hospitals on a different footing.

The PRESIDENT, in conclusion, thought the statement made during the discussion, that a hospital could not claim for treatment given to persons injured whilst motoring because it was a voluntary institution, was completely wrong. Such a hospital then became not a voluntary but a compulsory hospital, and he thought the hospital was entitled to make a claim.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 18TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 219 (last week 243); scarlet fever, 1446; diphtheria, 761; enteric fever, 87; pneumonia, 977; puerperal fever, 30; puerperal pyrexia, 105; cerebro-spinal fever, 7; acute poliomyelitis, 9; acute polio-encephalitis, 1; encephalitis lethargica, 28; typhus fever, 1; continued fever, 1; dysentery, 5; ophthalmia neonatorum, 159. There were no cases of cholera or plague notified during the week. The single case of typhus fever was notified in Bristol C.B.

The cases of small-pox were notified from the counties of London 1 (Hackney), Derby 6 (Derby C.B.), Durham 105, Lancaster 2 (Wigan), Northumberland 9, Nottingham 1 (Mansfield), Southampton 1 (Bournemouth C.B.), Yorks, North Riding 1, West Riding 46, Glamorgan 1 (Mountain Ash), and Monmouth 46. None was returned from Kent, Middlesex, Surrey, or the City of York.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 5 (0) from enteric fever, 39 (1) from measles, 5 (1) from scarlet fever, 15 (7) from whooping-cough, 13 (4) from diphtheria, 48 (11) from diarrhœa and enteritis under two years, and 31 (5) from influenza. The figures in parentheses are those for London itself.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs. T. Gwynne-Jones and E. S. Mellor to be Surg. Comdrs.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Capt. A. R. Brailey has been appointed an Honorary Surgeon to the King.

Proby. Surg. Lt. E. A. Gerrard to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. C. R. Sylvester-Bradley is placed on the half pay list on account of ill-health.

Capts. to be Majs. (Prov.): J. E. Brooks and H. G. Hobson.

ARMY RESERVE OF OFFICERS.

Lt. A. D. Gorman to be Capt.

TERRITORIAL ARMY.

Maj. (Bt. Lt.-Col.) C. R. Browne, having attained the age limit is retd. and retains his rank with permission to wear the prescribed uniform.

Lt. W. H. Roberts, late R.F.A. T.A. Res. of Off., to be Lt.

C. R. C. Moon, late 2nd Lt., R.F.A., to be Lt.

Supernumerary for Service with O.T.C.—Capt. D. McNeill, late R.A.M.C., to be Capt., supern. for service with the Med. Unit, Glasgow Univ. Contgt., Sen. Div., O.T.C.

INDIAN MEDICAL SERVICE.

Col. C. R. Bakhle to be Hon. Physician to the King, vice Col. J. H. McDonald, retd.

Col. G. Tate to be Maj.-Gen.

Lt.-Cols. G. Hutcheson and R. F. Baird to be Cols.

Capt. Manohar Lall Dhawan to be Maj.

Col. A. Pollock, Chief Medical Officer, East Indian Railway, has been appointed Hon. Surgeon to the Viceroy. Lt.-Col. H. W. Acton, Professor of Tropical Pathology and Bacteriology, School of Tropical Medicine and Hygiene, Calcutta, has been appointed Director of the School, vice Lt.-Col. J. W. D. Megaw on leave. Maj. N. C. Kapur has been appointed Civil Surg., Murshidabad. Dr. Muhammad Umar, M.O. in Immediate Charge, Sadr Hospital, Bijnor, to officiate as Civil Surg., Bijnor, vice Dr. F. W. Holmes on leave. Dr. M. V. Webb, Principal, Women's Medical School, Agra, has been appointed to act as Chief Medical Officer, Women's Medical Service, and Secretary of the Countess of Dufferin's Fund Council. Dr. Muriel Stowe, Second M.O., Women's Medical College, has been appointed as Vice-Principal of the Women's Medical School, Agra, vice Dr. M. V. Webb on deputation.

Maj. C. H. Fielding has been posted to duty in the office of the Inspector-General of Prisons, Burma, Rangoon. Dr. Kali Prasad Sinha, M.O. on reserve duty from Hardwar to Saharanpur. Dr. S. D. Mathur, M.O. in Immediate Charge of the Sadr Dispensary, Partabgarh, has been posted to Allahabad.

BRISTOL'S MENTAL DEFECTIVES.—The Bristol City Council has decided to provide a colony for mental defectives at Almondsbury, some eight miles from the city, at a cost of £250,000. A site of 126 acres has been acquired and the details have been settled with the Board of Control. Experience shows that at least 50 fresh cases come under treatment every year, and it is found that the existing system of housing patients in various institutions—some of them a long distance away—is expensive and unsatisfactory. It is stated, moreover, that there are cases at the mental hospital which clearly ought not to be there.

Correspondence.

"Audi alteram partem."

UNIVERSITY OF LONDON:
AN APPEAL FOR A SPORTS GROUND AND BOAT-HOUSE.

To the Editor of THE LANCET.

SIR,—May we appeal to the general public for support in a cause which, we believe, will directly interest a great number of your readers. That cause is the provision of a sports ground and boat-house for the University of London.

The student life of this great University—the largest in the Empire—has long struggled gallantly towards that ideal of unity which is its natural birthright. But the force of circumstance has so far been too strong to permit of complete success. Scattered as are her colleges and schools throughout the metropolis, and scattered as are her external students throughout the world, considerations of time, of distance, and of expense have proved a heavy handicap, and, moreover, until now London has lacked that which is possessed by nearly every other university in the land—the places of common assembly where all, by tradition and custom, habitually forgather.

But the tide is on the turn. Already, by the acquisition of the Bloomsbury site, a great centre has been provided for the development of the teaching, administrative, and social life of the University. If to that can be added centres for inter-collegiate and inter-university contests, whereby athletics both on land and water may advance, pari passu, with academic growth, the University of London will at length have come into her own, and through the loyalty and devotion of her students and graduates will take her proper place as one of the great educational rallying points of national and imperial unity. To achieve this purpose money is required—not a great deal in view of the importance of the object, but more than the University can find from her own resources. The present position may be summarised as follows:—

For the sports ground, 28 acres of grass land at Motspur Park, near New Malden, have actually been acquired, and for the boat-house, two acres at Chiswick. Taking into account the purchase price, together with the cost of initial outlay and the provision of an endowment fund to meet part of the annual running expenses, the total sum required is £74,000. Towards this £14,300 has already been privately subscribed, £12,500 of that amount having been provided within the University. For the remainder we now appeal, and in making our appeal we should like to add that the list of private subscriptions is headed by H.R.H. the Prince of Wales, who has graciously expressed his keen interest in the proposals and his hope that funds will eventually be forthcoming.

Cheques should be made payable to the University of London Athletic Appeal Fund Account, and forwarded to the Financial Officer, University of London, South Kensington, S.W. 7, who will gladly furnish any further information on the subject.

We are, Sir, yours faithfully,

ROSEBERY,
Chancellor of the University of London.
W. H. BEVERIDGE,
Vice-Chancellor of the University of London.
G. ROWLAND BLADES, Lord Mayor.
H. J. WARING,
June 22nd. Chairman of the Athletic Appeal Committee.

THE PERSISTENCE OF THE SLUM.

To the Editor of THE LANCET.

SIR,—I have read with interest the leading article in your issue of June 25th, and I am not sure that I agree altogether with your picture of the slum. I have come to dislike the use of the word, because in the minds of most people the wretchedness of the house has come to be associated with inevitable degradation in the occupants. This, I think, is far from being the case. A very fair proportion of the occupants of uninhabitable houses are, and have been in my experience, making the best of the circumstances in which they find themselves, and are not so far assimilated to their surroundings that they fail to reach a high standard when removed to new houses under rehousing schemes. I should say that about 60 per cent. belong to this category. There is a further 30 per cent. who oscillate, but who, on the whole, maintain a fair standard in their new surroundings. The residue belong to a class which is almost incorrigible.

People removed from uninhabitable houses are suddenly put in possession of facilities to which they have been quite unaccustomed, and it does not do to quarrel too violently with them if they are not immediately adaptable. This is not only a housing problem, but a considerable social experiment in which time must be allowed to enter as an ally. After all, personal and domestic cleanliness is a recently acquired notion, and I agree that enlightened management is the correct procedure. I also think that the "enlightenment" should be a function of a health department. This is recognised here and acted upon. The general supervision of the conduct of those rehoused from insanitary properties is carried out by the female sanitary inspectors' staff, while recently a special officer has been appointed, armed with the powers of a sanitary inspector, to undertake special supervision of those who most require it.

In Glasgow we have been dealing in the main with closely congested areas in which the chief defects arise from the closeness of the tenement buildings, which deprive one another of light and air. The vital statistics of these areas uniformly show that life under these conditions produces a high proportion of deaths from respiratory disease, particularly in children under 5 years of age, and also a high infant mortality. One quite definite result which these conditions produce is to throw the incidence of measles back into the very early years of life, when this affection is most fatal.

In the opening paragraph of your leader you say that a note of complacency has crept into official statements regarding the housing programme. I have seen statements as to overcrowding by medical officers of health which are anything but complacent in tone. As for Glasgow, the overcrowding in the small houses, of which the city is so largely composed (60 per cent. of the population live in houses of one and two apartments), has become an extremely serious problem. This has been contributed to by (*a*) the growth of large families in small houses, and (*b*) an increasing practice for two families to crowd into one house, mostly a two-apartment one, thus converting it into two single apartment houses. This practice of sub-letting one of the apartments in a room and kitchen house has become extremely common in many streets of the city. These features are, of course, associated with unemployment, but are in the main an index of the shortage of houses which can be let at a suitably low rental.

The two main problems, as I see them, are these: (*a*) improvement schemes—i.e., demolition of insanitary houses and the rehousing of the displaced occupants; and (*b*) provision of houses to relieve overcrowding among the stratum of the population just above the level of the former group. As regards (*a*), rehousing schemes do not add to the total available houses, and as regards (*b*), this very large group has so far received little relief from building programmes. The process of decantation, as it is called, has affected this group only to a small extent. Decontrol of houses, if it is followed, as seems likely, by a general increase of rents, will interpose an effectual barrier to this process of decantation.

Your leading article refers to the relationship of the home to the workshop, and is no doubt written with

the special problem of London in view. Every large town has its own peculiar difficulties in this respect, but I am satisfied that the general principle which should be applied in rehousing schemes should be ease of access to the open air in the interests of children, rather than proximity to work in the interests of the breadwinner. Cheap transport enters into this question, of course, and Glasgow, with its 2*d*. fare all the way and cheap intermediate stages, has gone far to meet this especial difficulty.

I am, Sir, yours faithfully,

A. S. M. MACGREGOR, M.D., D.P.H.,
Medical Officer of Health, Glasgow.

June 27th, 1927.

THE DISTRIBUTION OF LEAD COLLOIDS.

To the Editor of THE LANCET.

SIR,—We now consider it wise to remove all the existing restrictions in regard to the distribution of choriotrope—that is, of preparations of lead, which have been under our control for use in the treatment of cancer. So many variations are now being made on the continent and in this country—some of which appear to be useful—that we have no longer the power or the right to check the use, in skilled hands, of lead in the treatment of malignant disease.

We hope and believe that the profession is now fully alive to the dangers that may be associated with the casual administration of this material, and that it will be employed only by those who can carry out the treatment safeguarded by laboratory tests. At the same time it will be recognised that any preparation that may be placed on the market, including material issued under the special name of choriotrope which we have allowed British Colloids Limited (Crookes Laboratories) to register, will no longer be under our control.

In conclusion, I should like to express my appreciation of the courtesy and coöperation of British Colloids Limited during a difficult time; they have always been ready to sacrifice commercial gains in the interests of research and the public weal.

I am, Sir, yours faithfully,

Liverpool, June 24th, 1927. W. BLAIR BELL.

MECKEL'S DIVERTICULUM.

To the Editor of THE LANCET.

SIR,—Dr. C. S. McEuen's report of an interesting case of Meckel's diverticulum (THE LANCET, Feb. 26th, p. 436) induces me to give yet another instance of this relatively rare, seldom diagnosed, and always dangerous condition. On the fifth day after birth the native midwife attending a male child noticed that the cord was not shrivelling, and snipped it off close with a pair of scissors. As the wound at the navel did not heal the child was taken to a doctor, who applied a simple dressing and saw the case daily for over a fortnight. During all this time no escape of fæcal matter or flatus was noted either by the doctor or the parents. On the twenty-fifth day after birth the child was brought to the hospital presenting at the region of the umbilicus a bleeding bicornuate tumour covered by mucous membrane, consisting evidently of an everted portion of small intestine. The upper horn of the tumour measured six inches in length, while the lower portion projected less than one inch from the umbilical skin margin. All attempts at gentle reduction failed even under anæsthesia. On opening the abdomen the narrow fibrous remains of the diverticulum, through which the gut had prolapsed, was incised and the intussusception reduced. The child died a few hours later from shock. The possibility of such a condition arising is mentioned in Spencer and Gask's "Surgery" (1910 edition); it must, however, be regarded as rare, and, with the more widespread training of midwives, will become even rarer.

I am, Sir, yours faithfully,

E. H. R. ALTOUNYAN.

Aleppo, Syria, March 18th, 1927.

DIPHTHERIA IN LONDON.

To the Editor of THE LANCET.

SIR,—I have read with great interest your leading article of June 11th on the Prevention of Diphtheria in London, and my attention has been particularly arrested by the last sentence in the first paragraph of that article. Referring to Dr. Forbes's report you say "his figures show the incidence and mortality of diphtheria to be higher in London than in any other large city in Great Britain, and higher than that of almost any other European capital." Dr. Forbes's figures, being taken from official sources, are, of course, correct for the period covered by his report, but I respectfully submit that they are not a true picture of the conditions as they exist to-day, and that the sentence quoted from your article is less than fair to London.

From the five latest quarterly returns of the Registrar-General—i.e., for the period Jan. 1st, 1926, to March 31st, 1927—I have extracted the diphtheria notifications and deaths in eight cities in England and Wales with populations over 300,000, and have calculated the annual incidence of the disease, the case death-rate, and the annual death-rate per 100,000 persons living. These figures are here tabulated, together with the mean death-rate for Edinburgh, Glasgow, Belfast, and Dublin for the same period, and also the death-rate during the first quarter of this year, particulars of which are available, for those cities in Europe and America with over 1,000,000 inhabitants.

Towns and population in thousands.	Jan. 1st, 1926, to March 31st, 1927.		Case death-rate per cent.	Per 100,000 living.	
	Notifications.	Deaths.		Annual incidence.	Annual death-rate.
West Ham (316)	901	22	2·44	228	5·5
Leeds (473)	561	43	7·66	95	7·2
Sheffield (523)	1,331	65	4·88	203	9·5
London (4605)	16,914	666	3·93	293	11·5
Bristol (383)	930	59	6·34	194	12·3
Liverpool (863)	1,952	134	6·86	181	12·4
Birmingham (934)	2,846	146	5·13	243	12·5
Manchester (752)	1,403	139	9·90	149	14·7
Edinburgh (426)	—	56	—	—	10·5
Glasgow (1049)	—	166	—	—	12·6
Belfast (416)	—	56	—	—	10·8
Dublin (421)	—	93	—	—	17·6
Aggregate & averages (11,161,000)	—	1645	4·74	242	11·8
Towns with more than one million inhabitants:—	January–March, 1927 (three months).				
Hamburg (1111)	—	9	—	—	3·2
Chicago (3101)	—	86	—	—	11·1
Warsaw (1015)	—	29	—	—	11·4
New York (5924)	—	184	—	—	12·4
Paris (2871)	—	92	—	—	12·8
Berlin (1993)	—	81	—	—	16·2
Aggregate & average (16,015,000)	—	481	—	—	12·0

From the table three deductions can be drawn.

First, it is true that the incidence of diphtheria during these five quarters in London was higher than in any large town in England. Whether this high figure is due to the returns being uncorrected for errors in diagnosis, &c., I cannot say, but returns from other towns are doubtless on a similar footing.

Secondly, the case death-rates in London and in West Ham, which is included in greater London, are unquestionably the lowest of any large town in England which suggests that in the *treatment* of diphtheria London occupies a very high position. I am aware that a reduction of the incidence figures would increase the case death-rate, but again that argument applies all round. It is also possible that London may have experienced during the past 18 months an unusually mild type of diphtheria, but the returns give no hint

that this is so, and we must accept the figures as they are printed.

Lastly, the actual death-rate from diphtheria in London, which is a definite figure not subject to variation from any alteration in the incidence, is, with the exception of West Ham, Leeds, and Sheffield, lower than that of other large towns in England. Moreover, with the solitary and phenomenal exception of Hamburg, London for the corresponding period is bracketed with Chicago as having the lowest actual death-rate—11·1 per 100,000 living—of all cities in Europe and America of over 1,000,000 inhabitants, of which the figures are given. In view of these facts you may possibly see your way to modify the statement in the passage quoted.

I am, Sir, yours faithfully,

50, Beak-street, W. THOMAS MABEN.

IMPETIGO CONTAGIOSA.

To the Editor of THE LANCET.

SIR,—Dr. J. B. Ellison's interesting paper upon the treatment of impetigo contagiosa which appears in your issue of June 25th leads me to ask whether the use of the unguentum hydrargyri nitratis dilutum of the British Pharmacopœia in this complaint has entirely dropped out. Although I remember various letters and papers upon impetigo in your columns and elsewhere, during the last 20 years or so, in which various remedies have been advised, especially the ointment of ammoniated mercury, I cannot remember one communication in which the acid nitrate of mercury was mentioned. Between the years 1886 and 1890 I had a fairly wide experience of this treatment at St. Bartholomew's Hospital, the Victoria Hospital for Children, and the Kensington Dispensary, and I never came across a case which did not clear up within a week at the most under the (dilute) acid mercurial nitrate ointment, provided that the crusts were gently removed previously by hot fomentations. I have no experience of flavine, but as I see that Dr. Ellison says that the average time for cure is ten days I would ask him to try the older remedy. Contrary to what might be supposed this does not seem to cause any pain.

I am, Sir, yours faithfully,

Forest Row, June 25th, 1927. H. P. CHOLMELEY.

QUININE AND CHINOSOL SUPPOSITORIES.

To the Editor of THE LANCET.

SIR,—Although the quinine suppository is practically harmless and is entirely satisfactory to the majority of people, the details of the many thousands of cases carefully studied at the C.B.C. Clinic for Birth Control have confirmed the view promulgated by Dr. Marie Stopes in 1918 that a few women apparently absorb sufficient quinine to cause sleeplessness, slight digestive disturbances, &c. A still smaller percentage of men find the quinine irritating to the glans penis. As the C.B.C. Medical Research Committee has always had the desiderata of improvement in technique before it, this has been carefully considered, and we think that your readers (who are probably often called upon to recommend some contraceptive suppository) may be glad to know that a new type of suppository composed solely of cocoa butter and chinosol has been tested at the Clinic and over 800 cases have found it entirely satisfactory.

The manufacturing chemists, Messrs. Lamberts, have proved very helpful in preparing different strengths and manufacturing for experimental use, and chinosol suppositories may now be obtained from the usually recognised sources.

We are, Sir, yours faithfully,

E. B. TURNER, F.R.C.S., F.R.C.P.
MAUDE KERSLAKE, M.B.
GEORGE JONES, M.A., M.B.
MARIE C. STOPES, D.Sc., Ph.D., F.L.S.
H. V. ROE (hon. secretary).

June 24th, 1927.

ANÆSTHETICS AND INQUESTS.

To the Editor of THE LANCET.

SIR,—Your leading article on this subject will be cordially welcomed and endorsed by those members of the profession whose daily work affords them ample evidence of the disadvantages of the present system.

I opened a discussion on this subject at a meeting of the Section of Anæsthetics of the Royal Society of Medicine, which was reported in THE LANCET (1923, i., 849). On that occasion I expressed my opinion as to the unsuitability of the coroners' court for inquiries of this nature, and I dealt in detail with most of the points brought forward in your leading article. In this letter I desire to confine my remarks to the aspect of publicity. Later experience has convinced me beyond any doubt that the publication of deaths under anæsthetics serves no useful purpose whatever, but on the contrary is both directly and indirectly a danger to the public for the following reasons. That these reports frighten patients is an indisputable fact which can be testified to by any practising anæsthetist. The report of one of these inquests, which for some reason or other has attracted unusual attention, is invariably followed by an increase in the number of ultra-nervous patients who come under our observation, some of whom actually attribute their nervousness to the reports which they have read. This is a grave danger to the public because it so frequently leads patients either to refuse operation or to postpone it until it is too late, and in very many instances the patients tell us that they dread the anæsthetic rather than the operation. I am quite sure that this unnecessary fear of anæsthetics is more widely spread than it used to be, and that it is due to the increasing prominence which is now given to these matters in the lay press. Moreover, it is not sufficiently realised how much the public suffer from the *indirect* effects of this publicity. Only those who are habitually in touch with hospital work can fully appreciate the damaging influence which the fear of these reports exercises upon the anæsthetic work of the student and of the hospital house officer. It renders the administration of anæsthetics the most unpopular of the house officer's duties, and in consequence men are apt to shirk during their hospital life the very branch of work in which experience and self-confidence are most essential to the safety of their patients.

Wise discrimination in the choice of the anæsthetic is of enormous importance, but it is indisputable that the dread of the publicity attached to inquests often tends to influence the administrator to disregard the claims of chloroform because of its slightly greater "on the table" risk, and to give long administrations of ether to the type of patient who will almost certainly develop postoperative chest trouble in consequence. Unless chloroform is to be entirely banished from our list of anæsthetic agents, it is essential that students shall be taught how to give it, but the publication of coroners' criticisms on the use of this drug is steadily killing the teaching of its administration in London hospitals. Again, it is the public who suffer, for many students go out into practice without having had any practical tuition in the administration of this anæsthetic, which, although the most immediately dangerous, is, in the hands of a competent administrator, very often the best so far the ultimate recovery of the patient is concerned. Is it not also possible that in desperate cases the patient is sometimes deprived of the last—although possibly forlorn—hope of saving his life by operation, because of the public odium which follows a death on the table?

In conclusion, may I ask the protagonists of full publicity to tell us what single advantage the public can gain from reading reports of anæsthetic fatalities, which will counterbalance the very serious disadvantages and dangers which I have described.

I am, Sir, yours faithfully,

Harley-st., W., June 28th. J. HENRY CHALDECOTT.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

A Cancer Campaign in Ireland.

A PUBLIC meeting to inaugurate the National Cancer Campaign (Ireland) was held in the Royal College of Surgeons, Dublin, on June 27th, under the presidency of the Marquis of Dufferin and Ava, Speaker of the Senate of Northern Ireland. The origin and object of the Campaign were detailed by Mr. Louis Cassidy, F.R.C.S.I., who is honorary secretary to the committee. For four years past investigations into the treatment of cancer by deep X rays has been carried on at the Coombe Hospital. This work is now to be transferred to the Royal City of Dublin Hospital, in connexion with which a department for cancer research is to be founded. Investigation of other lines of treatment will also be undertaken at once. A committee has been formed of representatives of the University of Dublin, Queen's University (Belfast), the Royal College of Physicians of Ireland, the Royal College of Surgeons in Ireland, the Royal Dublin Society, the Royal Academy of Medicine in Ireland, the Joint Committees of the British Red Cross Society and the Order of St. John, and the Royal City of Dublin Hospital. Dr. T. G. Moorhead, Regius Professor of Physic in Dublin University, has accepted the post of honorary director, and Dr. Itami, of Osaka, Japan, who was formerly engaged in research work at the Cancer Research Institute in London, has been appointed assistant director. Other workers will soon be appointed. The Joint Committees of the British Red Cross Society and the Order of St. John has given a sum of £5000, and a private donor has given £6500, and various other subscriptions have been received. The object of the meeting on Monday was to gain the attention of the public to the movement and to appeal for funds.

Lord Dufferin, as chairman of the meeting, stated that the appeal was made to the whole of Ireland, and that the people of Northern Ireland might be counted on to contribute generously. His Excellency the Governor-General of the Irish Free State proposed the first resolution, declaring that the Cancer Campaign was worthy of the support of all citizens of Ireland. The resolution was seconded by Sir Humphry D. Rolleston, Regius Professor of Medicine at Cambridge, who spoke of the previous contributions of the Dublin school to the development of the science of medicine. Having shown the urgency of the need for research in regard to cancer, he said that to enable this research to be carried out in Dublin an institute with whole-time workers and proper equipment was a sine qua non; when this was fully realised the necessary funds, even in these times of distress, should surely be forthcoming to attract and keep in Ireland the keen mind and high ability that are recognised on the other side of St. George's Channel as the special product of Ireland.

Rev. Peter Finlay, S.S., proposed that a subscription list should be opened on behalf of the campaign. He said that it was a happy augury that though the meeting was being held in the capital of the Free State and that the research would be concentrated there, the coöperation which was hoped for, and which, as that meeting testified, was already given, was not limited by boundaries of place or politics or religion. It was fitting that it should be so, for the disease recognised no boundaries, and neither should the remedy nor the search for the remedy recognise any boundaries. He urged that an appeal for assistance should be made to both Irish Governments as well as to the public.

Prof. Harvey Cushing, who seconded the resolution, opened with the question to his hearers: "Do you realise that one out of every ten of us here assembled is likely to die of cancer within the next decade?" Unless Ireland differed greatly from other countries in the incidence of cancer, and unless the population was already on the alert to recognise the early manifestations of the disease and their significance, a cancer campaign was very much needed here as in other countries. It was no less important that through the agency of some central institution Irish experts and Irish hospitals should be enrolled in the general crusade against such a formidable disease.

Honorary Fellowship of the Royal Academy of Medicine of Ireland.

The Royal Academy of Medicine of Ireland held a special meeting on June 27th to confer its Honorary Fellowship on Prof. Harvey Cushing, of Harvard University. The general secretary presented him to the Academy in the following words:—

Sir PRESIDENT, LADIES, and GENTLEMEN,—I have the honour to present to you one who does not need any introduction to this Academy. I rejoice that this is so, for indeed I should be at a loss to describe him fittingly. Eminent as a physician, as a surgeon, and as a physiologist, he has taken the whole realm of medicine as his province, and in that realm all acknowledge him as a chief. Intellectually he towers among his fellows, as those of whom he has written tower physically among ordinary mortals. His brilliant work commands our admiration, but he has won our love and gratitude by enshrining for us in two noble volumes the memory of his great master, so dear to us all. Let us then, as a fellow-worshipper at the same shrine as ourselves, receive him gladly; let us honour our Academy by enrolling him a Fellow, and let us for himself receive him with our loudest plaudits. Harvey Cushing!

Prof. Cushing was then admitted a Fellow of the Academy by Sir James Craig, President, and he returned thanks for his election. He then delivered a brief address dealing with his recent experiences in electro-surgical work, particularly in cerebral surgery.

Honorary Degrees at Dublin University.

Honorary degrees were conferred at the Summer Commencements of Dublin University, held on June 28th, on Sir Humphry Davy Rolleston, Regius Professor of Medicine at Cambridge, and on Prof. Harvey Cushing.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—The eighty-sixth annual meeting will be held on July 18th to 22nd, under the Presidency of Dr. Hamilton C. Marr, at the Royal College of Physicians and the University, Edinburgh. On July 19th, in the morning, the annual meeting will be held. The Maudsley lecturer nominated for 1928 is Sir John Macpherson. In the afternoon the President will deliver an address on Dante and Rabelais: An Account of Two Mediæval Physicians, with a Summary of their Philosophy. On July 20th, in the morning, a discussion on Chronic Sepsis as a Cause of Mental Disorder will be opened by Dr. William Hunter; Sir William Willcox, Sir Berkeley Moynihan, Dr. C. Hubert Bond, Dr. H. A. Cotton, Dr. T. C. Graves, Lieut.-Col. J. R. Lord, Dr. W. F. Menzies, Dr. Adolph Meyer, and Dr. D. Chalmers Watson will speak. In the evening the annual dinner of the Association will be held at the Royal College of Physicians. On July 21st, in the morning, a discussion on Epidemic Encephalitis will be opened by Dr. Ivy Mackenzie, followed by Dr. J. G. Greenfield, Dr. R. M. Marshall, and Dr. G. Riddoch. Among the other speakers will be Dr. W. J. Adie, Dr. H. Devine, Dr. T. S. Good, Dr. E. Mapother, and Dr. W. A. Potts. On July 22nd, in the morning, a discussion on Points in the Lunacy Commission (England) Report—(1) What legal facilities are required for treatment? (2) How far is judicial intervention necessary? (3) What safeguards against improper detention are adequate?—will be opened by Prof. George M. Robertson. This discussion will be open to all interested in lunacy administration. The discussions will be held conjointly with the Section of Mental Diseases of the British Medical Association. In the afternoons visits will be paid to the Royal Hospital, Morningside, and to the treatment pavilion at Bangour Village, and an exhibition of work done in occupational therapy departments of Scottish mental hospitals. A memorial wreath will be placed on the bust of Pinel at Morningside at 9.45 A.M. on July 22nd by Sir H. Arthur Rose.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the third examination for medical and surgical degrees held recently the following candidates were approved :—

Part I., Surgery, Midwifery, and Gynæcology.—G. M. Addison, F. M. Allen, A. F. Alsop, R. Anderson, G. H. Barendt, W. J. H. M. Beattie, H. Bell, S. A. Belshaw, P. G. Bentlif, G. J. O. Bridgeman, W. A. Briggs, C. F. Brockington, A. C. Brown, H. B. Bullen, H. J. Burrows, R. W. Butler, C. P. Campion, A. B. Connell, E. C. Cosgrove, G. A. Eason, E. G. Frewer, R. Gallimore, H. Girling, A. R. Glover, E. W. Hayward, J. S. Hensman, W. G. S. Hopkirk, E. T. James, M. E. Lampard, L. C. Lancaster, A. H. Lankester, E. W. Lindeck, W. N. Maclay, F. J. Milward, J. K. Moore, J. L. Newman, T. St. M. Norris, M. D. Nosworthy, D. E. Oakley, C. D. Politeyan, J. C. C. Poole, E. J. Pye-Smith, M. G. P. Reed, J. H. Richmond, E. E. F. Rose, P. G. Salt, M. R. Sinclair, T. C. Stevenson, G. R. S. Stewart, C. L. Stote, J. R. H. Towers, C. G. Townsend, C. F. Watts, J. R. S. Webb, E. Whidborne, W. J. Wilkin, D. B. Wilson, E. C. Wynne-Edwards.

Part II., Principles and Practice of Physic, Pathology, and Pharmacology.—C. Adamson, E. S. Bolton, P. R. Buckton, R. C. L'E. Burges, H. J. Burrows, R. W. Butler, R. D. Curran, C. E. Donaldson, T. D. W. Fryer, H. K. Goadby, F. Goldby, A. C. Hampson, V. C. J. Harris, J. A. Hartley, A. S. Hollins, W. G. S. Hopkirk, F. S. Hubbersty, C. E. Kellett, F. Kellett, F. H. King, A. H. Lankester, T. F. McNair Scott, A. W. C. Mellor, W. J. Montague, G. M. B. Morgan, K. A. Muir, M. F. Nicholls, E. A. Nicoll, G. F. Oakden, C. J. Ormerod, C. L. Owen, R. Pearce, R. A. Phillips, W. P. Purvis, D. N. Rocyn-Jones, H. J. A. Simmons, L. A. P. Slinger, H. Smith, G. M. Tanner, C. I. Tuckett, C. W. Walker, R. Watson, C. F. Watts, R. W. Windle, C. E. Woodrow.

Degree of M.Chir.—R. S. Corbett, F. W. Roques.

At a Congregation held on June 21st the following degrees were conferred :—

M.Chir.—F. W. Roques.
M.B. & B.Chir.—T. S. Dewey.
M.B.—F. W. Law.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—S. A. Carr, Birmingham ; F. G. Hardaker, St. Mary's Hosp. ; S. Jenkinson, St. Bart.'s Hosp. ; H. I. Jones, St. Mary's Hosp. ; T. C. Lansdale, Guy's Hosp. ; H. S. Littlepage, Birmingham ; and S. K. Rigg, Bristol.

Medicine.—S. A. Carr, Birmingham ; R. P. Charles, King's Coll. and Charing Cross Hosp. ; T. C. Lansdale, Guy's Hosp. ; H. S. Littlepage, Birmingham ; D. D. Stidston, St. Mary's Hosp. ; and N. W. Wood, Middlesex Hosp.

Forensic Medicine.—G. Furniss, Manchester ; K. Girgis, Charing Cross Hosp. ; G. L. McDermott, St. Bart.'s Hosp. ; R. C. Pratt, Birmingham ; S. Slotar, Guy's Hosp. ; and S. le R. Switzer, London Hosp.

Midwifery.—K. E. Clarke, Charing Cross Hosp. ; G. Furniss, Manchester ; H. J. Harcourt, St. Thomas's Hosp. ; G. C. Rhys-Jones, Charing Cross Hosp. ; and I. O. B. Shirley, St. Thomas's Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery : S. Jenkinson, H. S. Littlepage, R. C. Pratt, S. K. Rigg, D. D. Stidston, S. le R. Switzer, and N. W. Wood.

UNIVERSITY OF GLASGOW.—At a Ceremony of graduation held on June 22nd the following degrees were conferred :—

Hon. LL.D.—Sir Charles Ballance (London), Prof. Murdoch Cameron (Glasgow), and Prof. Harvey Cushing (Harvard).

M.D.—With honours : Peter Laird M'Kinlay and Mary Macpherson Stevenson. *With commendation :* Mary Sloan Smith. *Ordinary degree :* William Simpson and William M'William.

Ph.D.—John Donald and Annabel Mary Tough Murray.

HARVEIAN SOCIETY OF LONDON.—A meeting will be held at the Star and Garter Hospital, Richmond, on Saturday, July 9th, at 4.30 P.M.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.—The annual oration of this society, which incorporates the London Dermatological Society, was delivered on June 22nd by Dr. H. Haxthausen, first assistant in the Skin Department of the State Hospital, Copenhagen, on Streptococcal Pityriasis. After a vote of thanks to the orator had been passed the annual general meeting of the society was held, and the following officers were elected for the coming session : Patron : The Earl of Chesterfield. President : Dr. Wilfrid Fox. Hon. treasurer : Dr. Knowsley Sibley. Hon. secretary and editor of Transactions : Dr. J. M. S. Scovell. The annual dinner was held at the Café Royal after the meeting. Dr. Haxthausen, Dr. J. H. Sequeira, Dr. J. A. Drake, Dr. A. M. H. Gray, Dr. Graham Little, Dr. H. MacCormac, Dr. W. J. O'Donovan, Dr. A. Whitfield, and Mr. Arnaudin were the official guests of the society.

EPSOM COLLEGE.—The annual general meeting of governors was held at the office, 49, Bedford-square, London, W.C., on June 24th, Dr. Raymond Crawfurd, the Chairman of the Council, presiding. The result of the elections to pensionerships and foundation scholarships was announced as follows, the scrutineers being Dr. Raymond Crawfurd, Sir Ernest Goodhart, and Dr. Seymour Taylor :—"Christie" pensioner : Charles W. J. Chepmell, 7411 votes. Ordinary pensioners : Fanny Dawson, 6798 votes, and Augusta M. Raper, 6456 votes. "Sir Thomas Smith" pensioner : Harriet E. Mullings, 5617 votes. Foundation scholars : John C. Stephens, 12,442 votes ; Charles H. F. Joy, 11,643 votes. The secretary reported that further vacancies having arisen, Dr. Edward J. Minchin, Mrs. Grace S. W. Dempster, and Mrs. Florence A. M. Swindlehurst would be appointed ordinary pensioners at a council meeting which would be held immediately after the annual general meeting. The Chairman moved the adoption of the annual report of the council to the governors, which showed that since the last annual general meeting W. J. Leaning had been awarded an open classical scholarship of £100 per annum at Pembroke College, Oxford ; C. E. C. Townsend had won an open Empire scholarship of £75 per annum at Loughborough Engineering College ; and E. A. Marsh had been awarded an open major scholarship in natural science of £100 per annum at Jesus College, Cambridge. Various important structural improvements have been made. The new chemistry block, which cost about £10,000, was opened by Viscount Grey of Fallodon on Founder's Day last year, and was in general use from the beginning of the Michaelmas term. The lower school annexe, providing washing, changing, and drying-room accommodation, which cost over £2500, had proved a great boon, and owing to the conversion of an old gymnasium near the lower school into class-rooms it had been possible to admit further boarders. The reorganisation of the heating and hot-water supply systems, which cost £8000, was completed by the opening of the Lent term, 1927, and the centralisation of these systems will result in a material economy in working. The funds for the provision of a new cricket pavilion, costing £3000, have been procured from old Epsomians, parents of boys in the school, the masters, members of the Council, and other friends of the College. A cordial vote of thanks to Dr. Raymond Crawfurd for the deep interest taken by him in Epsom College and its Royal Medical Foundation was moved by Mr. George E. Waugh, seconded by Dr. de Havilland Hall, and carried unanimously.

The Council will shortly award the following special scholarships :—

Leopold Salomons Entrance Scholarship.—The value of this scholarship is £50 a year, and it will be awarded to the son of a duly qualified medical man. Candidates must show an adequate standard of education for their age, and their financial position must be such as to make it impossible or difficult to obtain an education at Epsom College without the help of the scholarship.

St. Anne's Home Scholarship.—The value of this scholarship is £52 a year, and it will be given to a deserving and necessitous orphan daughter of a medical man who has been for not less than five years in independent practice in England or Wales.

Further particulars and forms of application for either of these scholarships can be obtained from the secretary, Mr. J. Bernard Lamb, at 49, Bedford-square, London, W.C. 1.

ST. THOMAS'S HOSPITAL MEMORIAL.—Last week the Duke of Connaught, President of the hospital, unveiled a large carved oak panel in the central hall in memory of those in the hospital who fell in the war, inscribed with the names of 74 students, a nurse, and 9 employees. Notwithstanding the recent opening of the students' residential club, it was thought fitting that the names of those who fell should be inscribed in the hospital itself. The Duke afterwards presented the Carnegie hero medal to Mr. Chisholm Williams, formerly a student of the hospital, in recognition of his services to radiology, of which he was one of the pioneers, together with a cheque for the first instalment of a pension from the fund.

NEW CONVALESCENT HOME FOR WIRRAL.—By the generous gift of their former residence at Noctorum, a suburb of Liverpool, as a convalescent home for children, Mr. and Mrs. Kielberg have added considerably to the facilities for the after-care of children. The Kielberg Convalescent Home, as the new institution is to be called, is affiliated to the Birkenhead and Wirral Children's Hospital, the pressure upon which will now be distinctly reduced. Not only have the generous donors given the house and grounds for this purpose, but they have also contributed considerably to the cost of necessary alterations and have promised an annual subscription of £500 for the next ten years.

THE Dame Louisa Aldrich-Blake memorial in Tavistock-square, London, W.C. 1, will be unveiled by Sir William Beveridge, Vice-Chancellor of the University of London, on July 4th, at 11.30 A.M.

A HOSPITAL FOR REDCAR.—The seaside resort of Redcar is growing so rapidly that it is considered that the time has come for it to be dependent no longer on the North Ormesby Hospital, ten miles away. A fund has recently been opened for the provision of a separate hospital.

SEAMEN'S DREADNOUGHT HOSPITAL, GREENWICH. Seven beds have now been endowed by the Seamen's Hospital Aid Committee since the end of the war. Mrs. Spencer Stidolph has just unveiled a tablet over the last of these in the Northumberland Ward, which has been dedicated to the memory of officers and men of the mercantile marine who lost their lives in the war.

PROPOSED HOSPITAL FUSION AT MIDDLESBROUGH.—A meeting is to be held shortly to consider the possibility of amalgamating the three large Middlesbrough institutions, the North Riding Infirmary, North Ormesby Hospital, and the Carter Bequest Hospital. Better accommodation is urgently required for convalescent patients where they can receive skilled treatment in pure air and pleasant surroundings.

NEW INFIRMARY AT DEWSBURY.—The foundation-stone of the new infirmary was laid at Dewsbury by Sir Mark Oldroyd. The new building will cost about £100,000, of which sum £70,000 has been promised and is in hand. The site chosen is close to the town, yet sufficiently removed from the main road to escape the noise of traffic. It will consist of two storys in blocks, so arranged as to obtain the utmost amount of sunshine. Sir Mark Oldroyd emphasised the desirability of maintaining the infirmary as a voluntary institution.

FURTHER HOSPITAL ACCOMMODATION FOR SWANSEA. Two recent additions testify to Swansea's determination to maintain its hospital reputation. A new isolation hospital on the most modern lines is in course of construction in place of a temporary building which has had to serve until now. It can accommodate 118 patients and a staff numbering about 40, and it is situated in a delightful district overlooking Swansea Bay. A new maternity hospital is being created out of an already existing building and 11 patients can be accommodated. The house stands in its own grounds with space for future extensions.

ORDER OF THE HOSPITAL OF ST. JOHN OF JERUSALEM. The King has sanctioned the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem: As Commanders: Dr. G. Locke, Lieut.-Colonel W. B. Cockill, Major J. Orton, Sir Berkeley Moynihan, P.R.C.S., Dr. U. Marks, Dr. C. J. R. MacFadden, Dr. I. G. Modlin, Dr. R. D. Thomas, Surgeon-Captain E. A. G. Wilkinson, R.N., Lieut.-Colonel F. T. Rees, Captain J. Anderson, Surgeon-Commander G. O. M. Dickenson, R.N., Dr. A. M. Ware, Mr. William C. Bentall, Colonel M. Maclaren, and Surgeon Vice-Admiral Sir Joseph Chambers. As Officers (Brothers): Dr. R. Laurie, Dr. A. H. Mackie, Captain G. W. Kendall, Dr. J. N. Robins, Dr. D. Holmes, Dr. R. J. Isaac, Colonel R. J. S. Simpson, Dr. R. J. Archibald, Dr. E. Llewellyn, and Dr. S. Williams. As Officers (Sisters): Dr. Margaret E. Lovett.

DONATIONS AND BEQUESTS.—Mr. Charles Herbert Millyard, Torquay, left £500 to the British Empire Cancer Campaign.—Mr. Russell Maule Stephenson, South Audley-street, W., left £500 each to the Cancer Hospital, Fulham-road, and the Hospital for Consumption and Diseases of the Chest, Fulham-road.—Mr. Duncan Graham Robertson, of Newbury, Berks, bequeathed £500 to Rossall School, Fleetwood, Lancashire; £500 to McLaren High School, Callander, to endow a bursary, and £200 to Newbury District Hospital.—Mr. H. Percy Shepherd, one of the city sheriffs, has given £1000 from the estate of his father for the Metropolitan Hospital Appeal Fund for the new nurses' home.—Dr. Alexander Laurence, formerly medical superintendent of the Cheshire County Mental Hospital, left estate of the value of £40,381. Besides various legacies, he left £250 to Chester Royal Infirmary, and the residue to his sister, and then to the Royal Medical Benevolent Fund.—Over £15,000 has been raised towards building a new hospital for Teddington and Hampton Wick.—Mr. Joseph Shoesmith, of Bright View, Halifax, Yorks, left £1000 each to the Royal Halifax Infirmary, John Abbott's Trustees Ladies' Home, and the Crossley and Porter Orphan Homes and Schools, and £2500 to other charities.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LANDLORD AND TENANT BILL.

DURING the discussion in Standing Committee B of the House of Commons of the Landlord and Tenant (No. 2) Bill a question affecting the interests of doctors and other professional men was raised.

On Clause 4 (which deals with compensation for goodwill) Sir R. LUCE urged the advantages of extending the Bill to professional as well as business premises. He said he would like to deal particularly with the medical profession and dentists. It had been said by a member of the Committee that there was no goodwill in the case of a doctor, but he (Sir R. Luce) did not agree with that contention. It was true in the case of a Harley-street surgeon or physician that he could not create goodwill by living in a particular house, because the goodwill applied to the whole street; but it was not the same thing in the case of a doctor who started practice in a small town. He might take a house which had not been built specially for the purposes of a doctor, but after he had occupied it for a certain length of time it became a valuable site as a doctor's house. By his occupation of it a doctor would increase the value of the house and create a goodwill for which he was as much entitled to compensation as any business man. The same observations applied to the case of a dentist. There was also the question of improvements. It frequently happened that a doctor who took a house was obliged to improve it in certain ways to meet the needs of his profession. It was almost essential that a doctor's house should have a garage, for instance; and in view of what was required of doctors under the National Health Insurance Acts a practitioner might be compelled to improve his surgery accommodation. If he was forced to do that at his own expense he was entitled to compensation when he left the house, because in all probability it would be taken by another doctor for whom it would have a special value in view of the improvements which had been made.

The CHAIRMAN: We cannot discuss the question of improvements now. We are dealing with the question of goodwill only.

Sir R. LUCE said he thought that it was understood that he might deal with improvements because the Committee were dealing here with a definition which raised the whole question of whether a doctor should come within the provisions of the Bill.

Mr. WOMERSLEY said he would like to support Sir R. Luce in his claim for extending the provisions of the Bill to professions, but he suggested that he should raise the matter when they came to Clause 12.

Captain HACKING (Under Secretary for the Home Office) said he thought that Sir R. Luce was quite right in raising this point at that stage because the words "or profession" would have had to be added if the amendment were made on Clause 12. He was afraid, however, that he could not agree with the arguments of the hon. Member. During the past few months he had been unfortunate enough to have been under many doctors, and he could assure Sir R. Luce that he did not go to a doctor in Harley-street because he was in Harley-street. He required to know something more about him than that before he paid him a visit. He did not think that a doctor or a dentist could leave goodwill behind. He happened to have as his medical adviser a brother of an hon. Member on that Committee. Quite recently he moved from one part of London to another. He (Capt. Hacking) did not go to the successor who came to his medical adviser's house, but he followed his own doctor to his new address because he liked him and had faith in him. It was very unlikely that he left goodwill behind him in the case of any other of his patients. The value of a doctor as an individual had to be taken into consideration, and none of his goodwill attached to his premises when he left. It was the determination of the Government not to extend the Bill to include the medical profession, and he must therefore decline to accept the amendment.

Sir W. PERRING said that in industrial areas there was a large number of men carrying on business as dentists in first-floor rooms situate above business premises. People had been in the habit of going to such dentists because they knew they were at a particular address, and if for any reason a landlord refused to renew the tenancy and a dentist left and another dentist came in his place, a large number of working people would go to his successor, having no notion of following a man about. There was no comparison between the case of a dentist in an industrial area and some specially distinguished dentist or doctor such as Capt. Hacking had

referred to. He (Sir W. Perring) dared say he would do the same as Capt. Hacking had done ; in fact, he had followed an oculist from one neighbourhood to another, but that was not the common practice of people in large industrial areas. He thought, therefore, that the Committee ought to look at this question from a different angle from that at which the Under Secretary had viewed it ; otherwise they might be creating hardship for a man who had built up a good business.

Mr. WITHERS said he hoped the Government would not consider the question of including the professions as being closed when the Committee came to the definitions, because there was really something to be said in favour of goodwill attaching to the professions.

Sir R. LUCE said that the Under Secretary had not replied to the question of the Bill applying to improvements made to the premises of professional men. He had given no reasons why a doctor who had been forced to improve his property very considerably should not be put in the same position as any other man who had had to improve his premises for business purposes.

The CHAIRMAN said that the question of improvements ought not to be raised here. It ought to be raised when the Committee came to Clause 12.

The amendment was negatived.

The Committee adjourned.

MIDWIVES AND MATERNITY HOMES (SCOTLAND) BILL.

On Friday, June 24th, the Midwives and Maternity Homes (Scotland) Bill, as amended in Standing Committee, was considered on Report.

Mr. BARCLAY-HARVEY moved the following new clause :—

"Where in any district there are not in operation arrangements made by the local authority for attending to the health of expectant mothers and nursing mothers, and of children under 5 years of age, in accordance with Section 3 of the Notification of Births (Extension) Act, 1915, the local supervising authority shall, upon receiving reasonable notice, provide the services of a midwife or a duly qualified medical practitioner for the purpose of attending a woman in childbirth, and the provisions of Subsection (4) of Section 22 of the principal Act shall apply for the purpose of the local supervising authority recovering such fee in respect of the aforesaid services as may be determined according to a scale fixed by the Scottish Board of Health as they apply to the fee paid to a registered medical practitioner called in in the case of an emergency."

He said that the object of Clause 1 of the Bill was to improve the service of midwives in Scotland. It had been urged in Committee that as a matter of fact in that clause they were not doing anything to help poor people to get maternity treatment, and this new clause had been designed to meet that point. It would now be possible to give this necessary assistance in all cases.

Dr. DRUMMOND SHIELS seconded and the clause was agreed to and added to the Bill.

Mr. BARCLAY-HARVEY moved an amendment to Clause 1 (Amendment of Section 1 (2) of Midwives Scotland Act, 1915) designed to ensure that improperly trained people should not be able to look after women in midwifery cases.

Mr. WESTWOOD seconded the amendment. He said that there was every desire in all parts of the House to pass this Bill, and as a result of long negotiations the provisions of this clause and this amendment had been accepted by all parties.

Mr. HARDIE said he wished to be sure on one point. There were some cases in Scotland where a neighbour went in to give some assistance in a midwifery case. If a fatality occurred would such a woman be brought under this Bill ?

Mr. BARCLAY-HARVEY : No, I think she is protected.

The amendment was agreed to.

On the motion for the third reading of the Bill,

Mr. MACPHERSON asked the promoters of the Bill whether they would not reconsider, when the Bill reached the House of Lords, Subsection (2), which says :—

"If any person being either a male person or a woman not certified under this Act attends a woman in childbirth otherwise than under the direction and personal supervision of a duly qualified medical practitioner, that person shall, unless he or she satisfies the Court that the attention was given in a case of sudden or urgent necessity."

Sudden emergencies arose, he said, very often in remote country districts where there was no doctor or certified nurse, and very often the crisis was dealt with through the neighbourliness of a woman living near. It was an extreme hardship that a neighbour who attended a woman in this way should be asked to go to court to explain why she so attended.

Dr. SHIELS said that Mr. Macpherson was evidently not familiar with the proceedings on this Bill. This matter had been thoroughly considered in Committee and both sides of the Committee had consulted together with a view to meeting the special difficulties in the Highland districts, and amendments had been inserted which, in the opinion of those best qualified to judge, entirely met the difficulty which the right hon. gentleman had put forward.

Mr. W. WATSON, the Lord Advocate, said that he quite appreciated the force of what Mr. Macpherson had suggested. Although, in form, Clause 1 provided that certain things constituted an offence, unless a particular defence could be set up they would only reach that stage if the Procurator Fiscal had decided that there was to be a prosecution. It really was important that in cases where a little friendly help had been given in an emergency there should not be a prosecution, and those who were familiar with the practice of Procurators Fiscal would rest content that they would never bring a case into court where only a little friendly help had been given.

The Bill was read the third time and passed.

POOR-LAW ADMINISTRATION IN WEST HAM.

On Monday, June 27th, the House went into Committee of Supply on a vote to complete the sum necessary for the salaries and expenses of the Ministry of Health.

Mr. GROVES moved a reduction in the vote of £100, in order to call attention to the administration of the new West Ham guardians. He said that the infantile mortality in the district had risen since the nominated guardians had been in office. In 1924 the infantile mortality-rate was 73 per 1000 ; in 1925 it was 65·9. In October, 1926, it went up to 82·4, and in November, 1926, it was 62·5. In all those cases the percentage was below the figures for the great towns of the country. In January of this year the death-rate rose to 100·4 ; in February it was 101 ; in March 104, and in April 104. In each instance these figures were above those of the great towns.

Miss SUSAN LAWRENCE said that the present board of guardians in West Ham had cut down the maximum amount of relief for a single person to 11*s.* a week. How was it possible for an old person to live on the balance, after paying 4*s.* 6*d.* or 5*s.* a week for rent ? The guardians claimed to have saved about £15,000 in salaries. They had done so, partly by making the nurses in the workhouse infirmary work longer hours. Their hours had been increased from 48—which prevailed in all good hospitals—to 56. That was a cruel proceeding on the part of the guardians, as the work of the nurses in this infirmary was particularly heavy. They had to deal with the worst venereal disease and cancer cases in London. Another result of the board's policy was indecent and unhealthy overcrowding. Since the relief had been cut down people had been sub-letting one of their rooms in order to take lodgers. On every humane ground the present West Ham guardians were to be condemned.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health), replying to the debate, said that with regard to the administration of the Blind Persons Act he could assure the Committee that considerable progress was being made. One test of the work that was being done was provided by the assistance afforded both by local authorities and the State. In 1921–22 local authorities were only contributing £14,600 in that respect, whilst this year it was estimated that it would be not less than £173,828. The contributions from the State in 1921 amounted to £69,886, whilst this year they were estimating £113,000 for the same object. He was glad to say that there had been no reduction in the assistance given from voluntary sources. In 1922–23 the total income of the 130 voluntary agencies, to which grants were given, was £378,535, and in 1925–26 it had risen to £420,463. He thought that it would be a great mistake to rely solely on the State.

As regards the position of affairs in West Ham, the 12 months' period for which the new guardians were appointed expired on July 18th next. So far from being dissatisfied, as some Members had suggested, with the administration of the new board of guardians, the Minister, and, he thought, the great majority in the House and in West Ham, took the view that these new guardians had carried out their work with great success, with great benefit to the district, and without doing any harm to a single deserving person. Holding that view, the Minister had taken the necessary steps to continue the appointed guardians for a further period of six months, which was the maximum period of extension allowed by the Default Act.

The motion to reduce the vote was defeated by 235 to 75.

PATENT MEDICINES DUTY.

On Tuesday, June 28th, the House went into Committee on the Finance Bill, Captain FITZROY, Deputy Chairman of Committees, in the chair.

On Clause 2, which proposes to make permanent the additional excise duty imposed on patent medicines by the Finance (No. 2) Act of 1915,

Sir R. HAMILTON moved that the duty should be extended only to August 1st, 1928. He said this duty was doubled in 1915 as a purely war measure, and the Chancellor of the Exchequer now proposed to keep that double duty for all time, and not bring it up for annual review as the amendment suggested.

Mr. R. MCNEILL (Financial Secretary to the Treasury) said this was not a tax that fell in any true and wide sense on medicine as understood to-day, because there was an exemption provision under which anything that came under the heading of a regular medicine recommended by a doctor escaped the tax. This very old duty was an anomalous one in many respects, and, if they were devising an ideal fiscal system, it was very likely that this particular duty would not find a place in it. But it had in fact been regarded by the public and the trade as unobjectionable. The only question raised by the amendment was whether the additional duty, which was put on during the war, should be put on a permanent basis or not. The original tax was on a permanent basis, and it would be an absurdity to have the other half on an annual basis.

Mr. HARRIS said that the tax was hidden from the public sight, and was therefore a very dangerous one. When people bought patent medicines they were often not conscious that they were making a contribution to the revenue. This was a war tax and ought to be reviewed. To say that the words of the Act of 1812, which governed the imposition of the duty, were suitable for the purpose, was to stretch the imagination. That Act contained four pages of patent medicines advertised as taxable, but not one in ten of them could be bought to-day in any chemist's or grocer's shop in the country. Before the tax was made permanent, the Committee should be quite clear that the words governing its imposition were founded on sound principles and intelligible to the public. The words in the Act of 1812 were out of date. He asked the Financial Secretary to the Treasury to reconsider the whole matter by next year and to redraft the governing words.

Commander O. WILLIAMS said he was not at all sure that almost as many people were not injured by drinking medicines as by drinking other beverages. He hoped that in framing next year's Budget the Chancellor of the Exchequer would consider the possibility of lowering the duty on British medicines and raising it on foreign medicines.

Sir E. HILTON YOUNG said that if a small fancy tax was not bad in itself, that might be a very good reason for not taking it off. No doubt very large profits were made by the vendors of patent medicines, very largely through the credulity and ignorance of their fellow countrymen. If a patent medicine was sold and contained nothing that was not in the ordinary Pharmacopœia then the unfortunate purchaser would be paying ten times more than the article was worth. In that case it was just that the vendor should make some contribution to the revenue. If there were some special knowledge or secret of manufacture contained in the article sold it was in the public interest that that secret knowledge should be placed at the general disposal of the whole medical profession. In the event of that not being done it was right that the vendor should pay for his retention of useful knowledge from the public benefit.

The amendment was rejected by 249 votes to 125.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 22ND.

Training of Midwives in Scotland.

Major MACANDREW asked the Secretary of State for Scotland what is the position with regard to a grant for Scotland in connexion with the training of midwives.—Sir JOHN GILMOUR replied: I have come to be of opinion that there is a need for further trained women in midwifery in Scotland, and it has been arranged to offer a training grant, not exceeding £20 per head, for nurses who have taken a full nursing training to the satisfaction of the Scottish Board of Health and who are now prepared to take the Central Midwives Board qualification and give an undertaking thereafter to give two years' service in Scotland. The total grant for the current financial year is limited to £2000.

Water-supplies and Lead Contamination.

Sir ROBERT THOMAS asked the Minister of Health whether he had any information regarding the danger to public health in districts where the water-supply is drawn from lead-bearing strata.—Mr. CHAMBERLAIN replied: I do not know of any district where there is such danger. Lead compounds are found in many different kinds of rock formation, but water naturally containing lead is very rare. Water which will act upon lead pipes is not uncommon, but precautions are taken where necessary.

Consultant and Specialist Medical Service.

Mr. HORE-BELISHA asked the Minister of Health whether any decision was reached at the recent consultation of his department with the consultative council regarding the recommendations made by the Royal Commission on National Health Insurance that the scope of the benefit should be extended to include a consultant and specialist medical service, and that the necessary funds for this purpose should be obtained by a partial pooling of future surpluses of approved societies.—Mr. CHAMBERLAIN replied: I have not yet received from the consultative council any expression of their views on the recommendations referred to by the hon. Member.

Medical Examination of Pauper Casuals.

Mr. FENBY asked the Minister of Health whether he had any evidence that boards of guardians were complying with the circular of his department suggesting that casual paupers should be periodically medically examined. — Mr. CHAMBERLAIN replied: The suggestion which I made was that a medical officer should periodically inspect the casual wards and should do so if practicable at a time when he could also see the casuals, so as to satisfy himself that they are free from disease. I have not received any special reports of the extent to which this suggestion has been put into practice, but I have no reason to suppose that it has not been effective.

THURSDAY, JUNE 23RD.

Poisonous Cosmetics.

Mr. DAY asked the Minister of Health whether he had received any reports from the officers of his department to the effect that many cosmetics being sold at the present time were poisonous and when applied to the skin might cause definite injury to health, and would he consider introducing legislation for the purpose of bringing the sale of cheap cosmetics, shampoo-powders, lip-sticks, and hair-dyes under public control.—Mr. CHAMBERLAIN replied: I have not received any such reports and I have at present no reason for supposing that any action on my part is required.

Infantile Mortality in London Boroughs.

Mr. WILLIAM THORNE asked the Minister of Health the infantile mortality in the boroughs of Poplar, Paddington, Kensington, Chelsea, Westminster, Marylebone, and West Ham for the year ending March, 1927.—Mr. CHAMBERLAIN replied: The most recent figures available are those for the calendar year 1926, which are as follows:—

	Deaths.		Deaths
Poplar ..	.. 71	Westminster	.. 61
Paddington ..	.. 86	Marylebone	.. 85
Kensington ..	.. 61	West Ham	.. 62
Chelsea ..	.. 65		

Deaths under 1 year per 1000 births.

Contamination of Ice.

Miss WILKINSON asked the Minister of Health whether his attention had been called to the conditions in which quantities of ice which might be used in drinking fluids were carted through the streets, and whether he would take powers to ensure cleanliness in the interests of public health.—Mr. CHAMBERLAIN replied: I am advised that the risks to health arising from surface contamination of ice under the circumstances to which the hon. Member refers are not such as to call for the institution of special measures.

Alleged Lax Certification by Doctors.

Mr. WHITELEY asked the Minister of Health whether his attention had been called to the inquiry held by the medical service subcommittee of the Durham County Insurance Committee into the question of lax certification by the doctors in the eastern part of the county during 1926, and, if so, whether he proposed to take any action in the matter.—Mr. CHAMBERLAIN replied: Yes, Sir. I have received a report of this inquiry, but in the absence of any specific recommendation by the Insurance Committee I am not in a position to take any action in the matter.

Orthopædic Treatment of Children.

Mr. BROAD asked the Minister of Health what local authorities undertook orthopædic treatment for children below school age; what authorities worked in conjunction with voluntary agencies; and whether in all cases the Ministry defrayed 50 per cent. of the cost to the authority.—Mr. CHAMBERLAIN replied: The councils of 35 administrative counties, 36 county boroughs, and 58 other boroughs or urban districts in England and Wales have made arrangements for the orthopædic treatment of children below school age, and all of them except one work in conjunction with voluntary agencies as respects the whole or part of their arrangements. In all cases but one, in which the cost is defrayed out of trust funds, a grant amounting to 50 per cent. of the approved net expenditure of the local authority on the service is paid by the Ministry.

Local Authorities and Accident Funds.

Mr. HAYES asked the Minister of Health what local authorities have set up their own accident and workmen's compensation funds in connexion with their trading

services.—Mr. CHAMBERLAIN replied: The general law does not empower a local authority to set up its own accident and workmen's compensation fund. I am advised that 46 authorities have obtained powers by local legislation since 1900 to set up such funds in connexion with their trading or other services, but I do not know to what extent the powers have been actually exercised.

Deaths of Women in Childbirth.

Sir WALTER DE FRECE asked the Minister of Health whether his attention had been called to the fact that the death of women at childbirth continued unabated; whether he could give the number of such deaths during the last ten years, indicating when the maternity benefit came into force; and state what, in the opinion of his medical advisers, were the grounds for the absence of any diminution of this type of mortality.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. The answer to the second part involves a tabular statement. The earliest date at which maternity benefit became payable was Jan. 13th, 1913. As regards the third part I am sending my hon. friend a copy of a report on maternal mortality, by Dame Janet Campbell. The following is the statement:—

England and Wales: Deaths of Women in Childbirth, 1917–26.

Year.	Births registered.	Deaths of women classed to pregnancy and child-bearing.		Deaths of women not classed to pregnancy and child-bearing, but returned as associated therewith.	
		No.	Rate per 1000 births registered.	No.	Rate per 1000 births registered.
1917	668,346	2,598	3·89	638	0·95
1918	662,661	2,509	3·79	2,529	3·81
1919	692,438	3,028	4·37	1,337	1·93
1920	957,782	4,144	4·33	1,086	1·13
1921	848,814	3,322	3·91	925	1·09
1922	780,124	2,971	3·81	1,051	1·35
1923	758,131	2,892	3·81	764	1·01
1924	729,933	2,847	3·90	849	1·16
1925	710,582	2,900	4·08	759	1·07
1926	694,563	2,860	4·12	709	1·02

The number of deaths of women in childbirth affords no indication of the trend of maternal mortality during the last ten years, in consequence of the abnormal variations in the number of births during that period. The numbers of births registered and the mortality of mothers per 1000 births have therefore been added.

Protection of Soft Fruit from Contamination.

Miss WILKINSON asked the Minister of Health if he would take powers to ensure that strawberries and other soft fruit difficult to wash without damage, should not be exposed to flies and the dust of the streets, but that some protective covering should be used.—Mr. CHAMBERLAIN replied: I will consider the hon. Member's suggestion.

Condensed Milk.

Lieut.-Colonel HOWARD-BURY asked the Secretary of State for War whether he would encourage the use of fresh milk, or condensed milk of British origin, in preference to the large amount of foreign condensed milk now used in the army.—Commodore D. KING replied: So far as War Office contracts are concerned preference is given to condensed milk of home manufacture, and for some time past no condensed milk of foreign origin has been purchased.

Lieut.-Colonel HOWARD-BURY asked the First Lord of the Admiralty whether he would encourage the use of fresh milk, or condensed milk of British origin, in preference to the large amount of foreign condensed milk now used in the navy.—Lieut.-Colonel HEADLAM replied: My hon. and gallant friend has been misinformed. The condensed milk purchased by the Admiralty is made in England. Fresh milk is supplied whenever practicable for use in Fleet establishments on shore and harbour ships.

Slum Clearances and Playing Fields.

Sir ROBERT THOMAS asked the Minister of Health whether, in schemes for the clearance of slum areas in poor parts of London, particularly the East End and the south side, provision was made not to rebuild on certain spaces, but to reserve them as playing fields.—Mr. CHAMBERLAIN replied: Schemes for the clearance of slum areas may provide for the reservation of part of a cleared area as an open space, and such provision has been made in some London schemes. It is usually found, however, in London, that the land is either too expensive or is required for carrying out the rehousing obligation under the scheme owing to the lack of other suitable sites which could be used for such a purpose.

MONDAY, JUNE 27TH.

Tuberculosis and Nephritis in the Navy.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty the number of ratings invalided from the Royal Navy in the year ending March 31st, 1927; and the numbers invalided for tuberculosis and for nephritis and other kidney and bladder troubles, respectively.—Lieut.-Colonel HEADLAM (Parliamentary Secretary to the Admiralty) replied: The figures for the year ending March 31st, 1927, are not available, but during the year 1926 (Jan. 1st to Dec. 31st) 1725 rating were invalided. In the same period the number invalided for tuberculosis was 197, but the figures for nephritis and other kidney diseases and bladder troubles will not be available for some months.

Fatal Small-pox Case at Hampstead.

Mr. GROVES asked the Minister of Health whether he was aware that the fatal case of small-pox from King Henry's-road, Hampstead, removed to the Dartford Small-pox Hospital, was a woman who had been vaccinated in infancy and revaccinated at the age of 11 years; and whether he could state the source of infection in this case.—Sir KINGSLEY WOOD replied: My right hon. friend is informed that this woman, who was 40 years old at the time of death, was said by her mother to have been unsuccessfully vaccinated in infancy, and was not revaccinated at the age of 11, her history in that respect having been confused with that of her sister. The source of infection has not been traced.

Schools for Mentally Defective Children.

Mr. HARRIS asked the President of the Board of Education what were the terms of reference to the departmental committee appointed by the Board to consider matters relating to mentally defective children; had the committee taken any evidence from witnesses; when was the committee likely to make its report; and, having regard to the fact that the development of schools for mentally defective children was being held up pending the findings of the departmental committee, had the Board any intention of asking for an interim report.—Lord E. PERCY replied: As regards the first part of the question, I would refer the hon. Member to the reply given by me on March 24th. I understand that the committee have not called witnesses, and that they hope to be able to report early next year. There appears, therefore, to be no occasion to ask them to consider making an interim report.

Mr. R. MORRISON: In view of the uncertainty among a number of local authorities as to what exactly is the policy of the Board of Education toward the provision of special schools for mental defective children, will the right hon. gentleman facilitate the publication of this report, or make some further statement so that local authorities may know exactly what they are expected to do?

Lord E. PERCY: No, sir. I do not think there is any uncertainty in the mind of the local authorities. Any authority which wishes to consult the Board can do so at any moment.

Mr. MORRISON: Does the right hon. gentleman wish the local authorities to understand that no further provision in the direction of schools for mentally defective children is to be made?

Lord E. PERCY: The hon. Member is not to understand that. He is to understand that the authorities are free to consult with the Board in connexion with any project for special schools which they have in mind.

Mr. MORRISON: Is the right hon. gentleman aware that a considerable number of local authorities have submitted plans for special schools for mentally defective children, and, as they have not met with the approval of the Board, they are in some doubt on the matter?

Lord E. PERCY: I do not think that after the communications they have had with the Board that they can be in any doubt at all.

School-children and Vaccination.

Mr. GROVES asked the President of the Board of Education whether his attention has been called to the action of the Newport education authority in excluding from the Newport secondary school a girl, 15 years old, on the ground that she was unvaccinated; and whether, in view of the ruling of the Board in the year 1909, and of the action it had taken in other similar cases, he would intervene on behalf of this school-girl and secure her readmission to the school.—Lord E. PERCY replied: My attention has already been called to this case by the hon. Member for Newport (Mr. Clarry). I understand that the local authority excluded this girl from the school on the advice of the school medical officer, acting in conjunction with the borough medical officer of health, owing to the prevalence of small-pox in the area outside the borough in which the girl lives, but that they are prepared to readmit her to school provided

that her parents are willing to allow her to live within the borough so long as the epidemic continues. In these circumstances I do not think that I should be justified in interfering with the action taken by the authority on the recommendation of their competent medical advisers.

Mr. LANSBURY asked whether this action did not really over-ride the Act of Parliament which enabled the parents of a child to decide whether or not it should be vaccinated.

Lord E. PERCY: It is entirely open to a parent to decide whether a child shall be vaccinated; but the law does not force any other parent, or those responsible for the children of other parents, to expose other children to risk.

TUESDAY, JUNE 28TH.

Wounds and Sickness among British Troops in China.

Lieut.-Colonel Sir FREDERICK HALL asked the Secretary of State for War what was the total number of troops of all ranks now in China; what was the approximate daily cost of maintaining this force; and how many casualties there had been from wounds, sickness, or other causes up to the present time.—Sir L. WORTHINGTON-EVANS replied: As regards the first part of the question, in addition to the normal establishment of three infantry battalions, there are at present stationed in China and Hong-Kong 17 infantry battalions and one marine battalion, with ancillary troops. As regards the second part, I would refer my hon. and gallant friend to the reply which I gave on May 2nd. As regards the last part of the question, 1 soldier has been killed, 2 officers and 9 other ranks have been wounded, and 9 other ranks have died as the result of illness or accidents. The average weekly number in hospital during the four weeks ended June 17th was 22 officers and 895 other ranks.

Lieut.-Commander KENWORTHY asked if the figure of 900 officers and men in hospital was not abnormally high?

Sir L. WORTHINGTON-EVANS: Very fortunately, it is not. The medical officers are very satisfied with the figures. The percentage is quite good.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, July 5th.—5 P.M., Notice for Fellows only. Annual General Meeting of Fellows. MacAlister Memorial: The new Episcope, forming part of the memorial to the late Sir John MacAlister, has now been installed in the West Hall. It is proposed to demonstrate its powers from 4.30 to 5 P.M. Tea will be served from 4.30 to 4.55 P.M. To elect by ballot the Officers and Council for the session 1927–28.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, July 4th, to SATURDAY, July 9th.—FELLOWSHIP OF MEDICINE DEMONSTRATIONS. Tues., 2 P.M., at Royal Chest Hospital, demonstration by Dr. Barty King. Tues., 2.30 P.M., at Central London Throat, Nose, and Ear Hospital, demonstration by Dr. Dan McKenzie. Those desirous of being present at this demonstration please notify hospital—Museum 1539. Fri., 5 P.M., at Royal Westminster Ophthalmic Hospital, lecture-demonstration by Mr. M. L. Hine, Iritis and Cyclitis. These demonstrations are free to all members of the medical profession.—CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. Special course in all branches of diseases of the chest.—NATIONAL HOSPITAL FOR DISEASES OF THE HEART Westmoreland-street, W. Intensive course.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Lecture-demonstrations at 5 P.M. daily throughout the week. Further information from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 4th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY,—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, July 4th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Dr. Ironside: Medical Out-patients.

TUESDAY.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Addison: Operations. 3 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Scott Pinchin: Medical out-patients.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 11 A.M., Mr. Simmonds: Orthopædic Department. 2 P.M., Mr. Donald Armour: Operations.

FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department and Ward Visit. 10 A.M., Dr. Owen: Medical Diseases of Children.

Operations, Medical, Surgical, and Special Out-patients Departments daily, 10 A.M. to 5 P.M. Saturdays, 10 A.M. to 1 P.M.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, July 7th.—4 P.M., Mr. Eric Lloyd: Acute Mastoiditis.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, July 5th.—3.15 P.M., Mr. A. M. Zamora: Mastoid Infections, their Complications and Treatment.

Appointments.

Bolingbroke Hospital, Wandsworth Common: HALDIN-DAVIS, H., M.D., B.Ch. Oxf., F.R.C.S. Eng., Physician Dermatologist; MARTIN, J. P., M.D. Belf., M.R.C.P. Lond., Assistant Physician Neurologist; VINER, G., M.D. Lond., F.R.C.S. Eng., Assistant Ophthalmic Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: SHEPHARD, W. H., L.R.C.P. Lond., M.R.C.S. (Sheerness District of the County of Kent); POMEROY, W., L.R.C.P. Lond., M.R.C.S. (Dursley District of the County of Gloucester).

Vacancies.

For further information refer to the advertisement columns.

Barbados Lunatic Asylum.—Asst. Med. Supt. £500.

Birmingham and Midland Eye Hospital, Church-street.—Physico-Therapist to Ultra-Violet Ray Dept. £100.

Birmingham University.—Walter Myers Travelling Studentship. £300.

Bradford, Royal Eye and Ear Hospital.—Res. H.S. £120.

Cardiff City Mental Hospital, Whitchurch, near Cardiff.—Second Asst. M.O. £350.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.

City of London Hospital for Diseases of the Heart, &c., Victoria Park, E.—H.P. At rate of £100.

Croydon County Borough.—Asst. M.O.H. and Asst. School M.O. £600.

Doncaster County Borough.—Asst. M.O.H. and Tub. O. £600.

Federated Malay States, Central Mental Hospital.—Second Asst. Med. Supt. £700.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. £50 for six months.

Indian Medical Service.—Appointments.

Infants Hospital, Vincent-square, Westminster.—Anæsthetist.

Kent Education Committee.—School M.O. £600.

Leamington Spa, Warneford General Hospital.—Res. H.S. At rate of £150.

Leeds City Sanatorium, Gateforth.—Res. M.O. £400.

Leeds Public Dispensary.—Jun. Res. M.O. £150.

Liverpool, Smithdown-road Institution.—Res. Asst. M.O. £200.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At the rate of £120.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Hon. Asst. Gynæcologist.

Mitcham, Eagle House.—M.O. £1 1s. per visit.

Nelson Hospital, Merton, S.W.—M.O. At rate of £100.

New Delhi, India, Lady Hardinge Medical College.—Clin. Pathologist. Rs.450 per mensem.

Rochford Union.—Dist. M.O. and Public Vaccinator. £120 and vaccination fees.

Royal Army Medical Corps.—Commissions.

Royal College of Surgeons of England.—Examiner in Dental Surgery.

Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. £100. Asst. P. to Electro-Light and Massage Depts. Also Hon. Anæsthetist.

Royal London Ophthalmic Hospital, City-road, E.C.—Hon. P. Also Second H.S. At rate of £125.

Royal Northern Hospital, Holloway, N.—Surg. to Ear, Nose, and Throat Dept. Also P.

St. Paul's Hospital for Diseases of the Genito-Urinary Organs, Endell-street, W.C.—Res. M.O. and H.S. At rate of £200 and £150 respectively.

Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. At rate of £150.

Stockport Infirmary.—H.S. and H.P. Each £175.

Stoke and Wolstanton Union.—Second Asst. Res. M.O. £200.

Stoke-on-Trent, City of.—Chief Tuberc. O. £750.

Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst. Bacteriologist. £E.720.

Sunderland County Borough.—Asst. M.O. for Maternity and Child Welfare. £600.

Swansea County Borough.—Asst. M.O. £600.

West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Reg.

West London Hospital, Hammersmith-road, W.—Res. Asst. S. £200.

Willesden General Hospital, Harlesden-road, N.W.—Phys. in Charge of Dept. for Dis. of Skin. Also H.S. At rate of £100.

Wolverhampton and Staffs Hospital.—H.S. At rate of £150.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Darlaston, Staffs, and Warlingham, Surrey.

Births, Marriages, and Deaths.

BIRTHS.

HABGOOD.—On June 23rd, at Wolverton House, Old Wolverton, Bucks, the wife of Arthur H. Habgood, D.S.O., M.B., of a son.

HIGHMOOR.—On June 21st, at Litcham, Norfolk, the wife of R. A. Highmoor, M.A., M.B., of a daughter (stillborn).

MACGILLIVRAY.—On June 25th, at Palmerston-place, Edinburgh, the wife of A. G. MacGillivray, M.B., Ch.B., High Hesket, Carlisle, of a daughter.

PLIMMER.—On June 24th, at Marloes-road, W., the wife of John Plimmer, F.R.C.S. Edin., of a son.

MARRIAGES.

MCFADDEN—SANTOS.—On June 20th, 1927, at Shaw Parish Church, Newbury, by the Rev. Kingsley Kefford, assisted by the father of the bridegroom, George Dickson Fisher McFadden, M.Ch., F.R.C.S. Eng., fourth son of the Rev. Jackson and Mrs. McFadden, of Badoney Manse, Newtownstewart, to Gasparina Amelia, youngest daughter of the late Mr. Antonio Luiz dos Santos and Mrs. Santos, of Rio de Janeiro, Brazil. At Home, 12, College-gardens, Belfast, Sept. 12th, 1927.

MORTON—SCOTT.—On June 18th, at Free Church, Hampstead, Garden City Suburb, Robert Morton, M.B., Ch.B. Glasg., to Anita Ballantine, only daughter of the late Charles F. Scott, Glasgow, and Mrs. Scott, London.

REID—WYMAN.—On June 25th, at Holy Trinity Church, Brompton, Andrew McKie Reid, *M.C.*, F.R.C.S., of Liverpool, to Clodagh, only child of Major Ronald Wyman, T.D., J.P., and Mrs. Wyman, of Thurloe-square, London.

ROBERTSON—PALMER.—On June 24th, at St. Mary's, Sullington, John Robertson, M.A., M.D., to Evelyn May, elder daughter of the Rev. Canon Palmer.

ROWLANDS—EVANS.—On June 23rd, at the Welsh Presbyterian Church, Mile End, London, John Jenkin Rowlands, M.R.C.S. Eng., L.R.C.P. Lond., to Eleanor Evans, grandchild of the late Rev. John Evans, Abermeurig, Cardiganshire.

DEATHS.

DAWSON.—On June 26th, at 46, Queen-street, Edinburgh, James Walker Dawson, M.D., D.Sc., F.R.C.P., F.R.C.S. Edin., aged 57 years.

HIGGINSON.—On June 26th, at a nursing home, after an operation, Charles Gaskell Higginson, M.D., M.A., of Portland-road, Edgbaston, aged 68.

KENNAN.—On June 20th, of pneumonia, Richard Henry Kennan, M.D., F.R.C.S.I., of St. James's-road, Liverpool, Medical Adviser to the Colonial Office, aged 59.

SIMPSON.—On June 20th, suddenly, at Walmer, after an operation, John Simpson, M.D., late of Carleton-road, Tufnell Park, London.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Mr. W. R. Morris has been elected President of the Radcliffe Infirmary in place of the late Lord Valentia. Mr. Morris, who has lived all his life in Oxford, has long been a vice-president of the hospital.

Notes, Comments, and Abstracts.

THE BOTTLE OF MEDICINE.

Being an Abstract of an Address delivered before the Hunterian Society

BY W. THOMSON BROWN, *M.C.*, M.B. EDIN.

BOTTLE-GIVING is felt to be an unsatisfactory part of medical practice. In operative surgery we walk by sight and not by faith; in preventive and pathological medicine we have theories which seem on the whole trustworthy and fruitful; but in treatment by medicines we have next to no system. We seem still to be (as they say) ignorant empirics, our only dicta *sentire est scire* and *post hoc, ergo propter hoc*, and our only safeguard from these fallacies the collection of statistics to establish a correlation between drug and result.

Pharmacologists and Clinicians.

It is not to be wondered at that there are differences of opinion. "Where knowledge is most imperfect," said Samuel Gee, "there are sects most numerous," and the imperfection of our knowledge includes ignorance of the nature and causes of disease, of the mode of action of drugs in disease, and of the indications properly to be met by drugs. We further find great difficulty in predicating anything of an exact nature when the factors in the recovery of health are so complex, and when even in the very act of dispensing physician, patient, and bottle form an inseparable trio.

As a way of escape from this all too human trinity we turn first to the pharmacologists. But here we too often find that they are ploughing with our heifers. We find a drug clinically useful; they will then try to give experimental proof of its action and loci of action. Their experiments sometimes assist the intelligent use of a valuable drug, but their negative results do not outweigh clinical opinion. The experimentalist himself is often an undisciplined theorist and sometimes at best discovers only an empirical remedy or diagnostic trick. Pharmacology has, however, done one important service to drug therapy in its translation of the ancient doctrine of signatures. We no longer justify by some fanciful association of form or origin the use of foxglove for cardiac disease, of walnut shells for head injuries, or of powdered mummy for prolonging life. We have transferred the signature from the plant to the molecule of its active principle. We now uphold a relation between action and chemical constitution, and MacDonagh maintains a relation between action and the electrical charge of the active atom in the molecule. These generalisations have led to the discovery of many new and valuable drugs and dyes. There is the further difficulty of the right use of drugs. "The chief weakness of medicine," said Sydenham, "is not our ignorance of the ways and means by which certain indications may be satisfied, but our ignorance of the particular indications that want satisfying. How I can make a patient vomit and how I can purge and sweat him are matters which a druggist's shop-boy can tell me off hand. When, however, I must use one sort of medicine in preference to another requires an informant of a different kind, a man who has had no little practice in the arena of his profession." Collective experience helps us somewhat. We see the wisdom of not giving drugs to spoil a diagnosis, to remove incentives to causal treatment, or to remove a beneficial symptom. Affirmatively, we use drugs to attack the chief associated factors in disease, to break a vicious circle, to control an automatic habit, to remove a complication retarding recovery, or, in many disorders, to obtain desirable and predictable results.

Theories.

There is no doubt that the significance of the bottle depends greatly upon what theory of disease we hold; and we all have theories. "Theorising in physic is unavoidable," said Cullen. "Every practitioner has proof of the propensity and presumption of his patients in this respect and among physicians themselves, though they can declare that Paracelsus was a knave, Van Helmont a madman, and Descartes a fool, and that all theory is nonsense, yet I find that they certainly employ it themselves . . . . The persons who employ it may not perceive they are using theory, but they are, and that of a bad kind too." Yet a poor theory is better than none and is often highly fruitful in discovery. Generalisations—and not the mere collection of therapeutic tips and wrinkles—are the main glory of medicine. "The vision is the virtue."

Perhaps the most striking feature of present-day theory is the conception of relativity. We no longer conceive

of things as endowed with their own power, but view everything in terms of relations. The worth of life no longer depends upon the liver. Diseases are functions of interdependent variables, such as man, microbe, and environment. Drugs are not expected to act as in health so in disease, as in one patient so in another. The *vis medicatrix naturæ*, personality, and the will no longer seem autonomous powers. We are compelled to study a patient and his environment as a whole. We realise that vomiting may be due to an indigestion of food or an indigestion of experience; that digitalis not only relieves a dropsy but reconstitutes a mental state; that very many factors are involved when a patient recovers health. Physician, bottle, patient, and environment form an almost inseparable complex group of relations, and hence, in the words of J. A. Lindsay, "there are few things more difficult than to establish a fact in therapeutics."

How Do Drugs Act?

Sceptics argue that: (1) "Nature heals the disease while the remedy amuses the patient"; or (2) the self-healing power is favoured mainly by externals—e.g., nursing, rest of mind and body, abstinence from food; or (3) the doctor's personality and not the drug sets the self-healing power in motion. These objections are a testimony to our ignorance of prognosis. Patients vary, germs vary, environment varies, and prognosis varies with them. The only perfect control for the therapeutic experiment, the patient himself, is of necessity excluded. All the same our profession claims to possess a fair degree of discrimination in these matters. Collective and personal experience in time do give us some conviction of the individual merits of nature, nurse, and medicine, and I should think a good many of us would say that the older we get the firmer becomes our faith in medicines. If the faith of some of us approximates to a mere dependence upon drugs, it is, perhaps, considerations of the suggestive power of personality, of the bottle as a vehicle of suggestion, of the successes of homœopathy, that make us doubt any but our own individual clinical results, that make us doubt even them.

Are the effects of all but a few drugs merely suggestive effects? It is hard to answer. But here I may note one curious fact. Some convinced sceptics about drugs have the most profound and wilful ignorance of psychotherapy. Believing that the drugs they use act only by virtue of personality and suggestion, they simultaneously declare that psychotherapy is synonymous with charlatanry. Would it not be better consciously to make a rational psychotherapy a part of rational medicine; would not the scope of drug therapy be rendered more manifest thereby?

Psychotherapeutic Weapons.

If personality and suggestion do the work of the bottle, how do they do it? To begin with, personality is not a mystic power residing in the doctor, but merely a set of relations between doctor and patient. That which impresses a patient favourably enhances medical personality; that which gives a contrary impression diminishes it. To a large extent one makes one's personality with a patient as one proceeds with him; personality is a suggestive technique. A "good bedside manner" is a developed medical personality. Again, this suggestive technique, dispensed along with the bottle must, to be therapeutically useful, benefit the patient's body. The patient's reaction to suggestion must be a total reaction of mind and body; his apprehension, his taking-of-it-all-in, must have a bodily expression. We find such total reactions in what we popularly term emotions. These emotions reified in names like fear, joy, anger, grief, are named from the subjective aspect, but as we meet them clinically they are bodily modifications to be interpreted, or for the purpose of suggestion, bodily modifications to be induced. Of these the two great therapeutic groups are ease of mind and confidence. "In quietness and confidence shall be your strength," said Isaiah. In terms of bodily expression, ease of mind admits of muscular relaxation, confidence of settled coördinated activity. Ease of mind is induced by rational means by widening the relations of the patient's consciousness to that end; confidence chiefly by proceeding from one accepted fact or truism to another. A degree of both emotions may be induced by giving a bottle, but reasoning is incomparably more powerful.

Now let us apply all this to the treatment of a case of nulliparous dysmenorrhœa without local abnormality. (1) We may give drugs for the symptom (aq. menth. pip., or a coal-tar derivative) and the patient is relieved. (2) We may suppose a fault in the endocrine system and try a bottle of tablets supposed to supply hormonic deficiency. The patient is not infrequently benefited. (3) We may take a wider view and say: This pain is the genuine sign of a real bodily disturbance. Of what bodily disturbances altogether is this girl the subject? We inquire as to conditions of work or of home life; as to visual or general fatigue. Is there anæmia present, oral sepsis, or constipation? We prescribe rest, a holiday; iron and arsenic, laxatives, or a visit to the dentist or oculist. Again the patient benefits. (4) If not lucky so far we may call in the surgeon; but perhaps we are premature: our diagnosis of bodily disturbance is still incomplete. What of the bodily expression of fear, hatred, and disgust? If the patient confess to a lively degree of such emotions, she should be given reasons why she should feel none of them towards the body generally, towards periods or towards sex. Here, again, the treatment is strikingly beneficial—so successful, indeed, that I believe there should be a place in classification for emotional dysmenorrhœa.

In my own experience I have known cases in which the simple discussion of confessed enduring emotion was the necessary antecedent to rapid recovery—e.g., a case of chronic hoarseness (duration two years); cases of loss of weight (on the average a stone being gained in a month); a case of cardiac insufficiency in mitral stenosis (marked dyspnœa on climbing a stair before treatment; after treatment, ease in spring-cleaning a house); a case of hemiplegia in cerebral embolism from aortic valvular disease (hemiplegia removed in 20 minutes; the finer movements of the hand remained paralysed); a case of enlarged thyroid with tachycardia (three months treated at a heart hospital, restored to normal in both respects in three weeks by talk).

It is clear that we have to study patients as a whole; in many cases the drug, in others the emotional comfort of tangible treatment, in others the deep comfort of "reasoning together" are indicated separately or in combination.

Lay Criticisms.

We are told by apparently intelligent lay people that all drugs are harmful and ought to be abolished, this being coupled with the question: "Why do you give poisons to people to make them well?" Shakespeare makes Timon of Athens say to the thieves—

> "Shun the physician,
> For his antidotes are poison, and he slays
> More than you rob."

It is only fair to say that there has been a medical school of therapeutic nihilists—doctors who advised the disuse of drugs altogether and a return to expectant treatment. Hoffman invented Hoffman's anodyne, but lived to say: "Fuge medicos et medicamenta, si vis esse salvus"; Addison often forgot to prescribe; Skoda used to say, when treatment was suggested, "Ach, das ist ja alles eins"; Hebra used "to feign treatment to prove that skins got well"; Hahnemann had a period of scepticism before he introduced the small dose; Sir William Gull affected a bread pill.

In reply we may say that the number of valuable drugs is, unfortunately, quite small; "drugs are seldom enough by themselves without other treatment, drugs are often of little use, drugs may be given in toxic or lethal doses, but we refuse to admit drugs are never of any use" (Gee).

There will always be diseases, and any method of attacking them which experience finds to be useful is worth exploring to the limit.

There is no clear line of demarcation between foods and drugs in respect of harmfulness. It is admitted that drugs can be given by fault, ignorance, or inadvertence so as to do harm to a patient. Yet in the sense of what goes into our poison cupboards, a poison is merely a word, a convenient label to group together substances, whose toxic dose is very small. In the sense of harmful to the body as a whole, drugs become poisonous by excessive dose in a given form to a given patient in a given time. We do not give poisons except by mistake, chiefly when the therapeutic and toxic doses lie very close together, or, in a few persons, when the toxic dose is less than the average therapeutic dose, or when a drug with an intended beneficial action has a dangerous subsidiary action, or when a toxic dose of a substance is formed in an incompatible mixture.

It may be remarked that it is an inadequate form of speech to say "I treated the patient with bromide and digitalis," or "I gave him a purge," when the result was unknown. We do not give digitalis simply; we are called upon to give suitable doses of digitalis in a given form to a given patient. There is much scope here for individual experience. Bromides, digitalis, belladonna, sodium salicylate, afford striking examples of action varying according to circumstances.

A patient of mine had non-cancerous jaundice and enlarged liver for some months. She consented finally to see a specialist whose prescription did no good. In desperation she dosed herself with 8 gr. of calomel. The jaundice disappeared, but she was confined to bed for several weeks afterwards with symptoms suggesting cerebral thrombosis from lowered blood pressure. She is now doing well and her liver is no longer enlarged; but she confessed that she

would have changed her doctor at once had I dosed her like that.

Popularity of the Bottle.

The newspapers tell us that patients, especially panel patients, take too much medicine. "Humbug gives it; 9*d.* for 4*d.* buys it; and superstitious credulity gulps it down." Every great Panjandrum in the friendly society world is in agreement with this. Panel patients take home bottle after bottle for so many weeks on end that I expect we shall soon return to the fine eighteenth century custom of including in the dower of a bride a good large silver medicine-spoon. But what is the general practitioner to do? In general practice treatment is dictated by the patient, and patients, as Epictetus said, "are displeased with a physician who doth not prescribe for them and think he gives them over." Similarly, in surgery it may be good practice to open a quinsy—but not everybody's quinsy.

An old lady came to me for several weeks getting medicine. I finally said: "Age will not be denied; medicines cannot cure you. In the absence of any acute symptoms I should spend your money on better things than drugs." She merely went to my partner for medicine and never called me in again. Is my idea of truth to be pushed into people willy-nilly? Are incurables to be called incurable to their faces? Some people cannot bear the truth; some will not have it. So we give a bottle, and so doing we satisfy the patient, we save trouble in investigation, according to the old jibe, "mist. gent. alk. and no proper diagnosis"; we cover our ignorance, we use a handy vehicle for helpful suggestion, *and* we get the man's money, and righteously, too, because we feel so orthodox about it! The patient gets bismuth and soda, kaolin, or alcohol, and does not need to stop smoking; his troubles are diminished, he has something to lean on; the responsibility is off his shoulders. He is glad that the doctor "doesn't want to know too much" and he gets something for his money besides talk. "It's easy to talk," he will say, "but that stuff was worth a guinea a bottle."

People hate to be improved, to have their illusions bluntly dispelled. A patient of mine was intensely angry at the recent exposure of a wonder-working proprietary remedy which her daughter was using. She said it ought not to have been allowed—taking away people's faith like that. She was sure that the paper which exposed the facts had grievously harmed many a poor consumptive.

It takes years to educate the public, and no one can be educated against his will. Some drugs are manifestly of use, why not all? "My doctor knows what to give me if yours doesn't." Bring up a child on the bottle and when he is old he will not depart from it. The bottle will never be abolished, but let us, in prescribing its contents, bear in mind Roger Bacon's list of impediments to knowledge: too great dependence on authority; allowing too great weight to custom; fear of offending the vulgar; and the affectation of concealing ignorance by the display of a specious appearance of knowledge.

ORTHOPÆDIC NURSING.

NURSES who have to do with the clinics for crippled children, which are now scattered over many counties, will be interested in a little book recently published by Miss E. C. Pearce.[1] The author's training and experience have been such that we may be sure that a handbook by her on this subject will be sound and practical. In the introductory chapter Miss Hunt characteristically lays stress on what she considers to be the duty of the orthopædic nurse. Not only is the latter to carry out the orders of the orthopædic surgeon and generally supervise instruments and splints and their management, but she is to teach mothers how to feed, clothe, and discipline their children. Miss Pearce makes good use of the small space at her disposal, and deals briefly with anatomy and with the diseases and deformities included in the specialty. To an appendix is delegated the important subject of the application of plaster-of-Paris, the nursing of patients in splints and jackets, and the preparation of the skin before operation. Some of the space taken up by descriptions of diseases and deformities, which the nurse does not have to diagnose, might well have been devoted to a fuller account of splints and plaster and their management. Much of the surgeon's work may be rendered vain if the nurse is not quick to recognise the first signs of undue pressure or friction, and if she does not know how to obviate or relieve such troubles. The page and a half on displacement of cartilages at the knee-joint seem to us superfluous in such a work.

Miss Pearce's book should prove very useful to those for whom it is intended.

[1] A Text-book of Orthopædic Nursing. By Evelyn C. Pearce, Sister Tutor, Fazakerley Hospitals and Sanatorium; and Agnes Hunt, Surgical Home, Oswestry. With a foreword by Sir Robert Jones. London: The Scientific Press. Faber and Gwyer, Ltd. 1927. Pp. 155. 5*s*.

CLINICAL PATHOLOGY AND THE USE OF STAINS.

IT is a complaint commonly heard from the busy practitioner that much as he would like to make use of them he has no time for the practice of the aids to diagnosis afforded by laboratory methods. So far as the more elaborate procedures are concerned this is no doubt true enough, but probably a good many of the medical men who make the complaint fail to realise how simple and how quickly and easily carried out are many of these miscalled laboratory procedures. The British Drug Houses have performed a valuable service in publishing a small pamphlet drawing attention to the simpler methods of clinical pathology and setting forth their technique. To the pamphlet is appended a list of standardised dyes and other reagents in common laboratory use from which the practitioner can make his choice. The inclusion of some procedures, such as the preparation of paraffin sections, suggests a somewhat optimistic view of the time at the disposal of the average practitioner, but much of the technique described could be carried out by any medical man in his consulting room. This kind of work would add new interest to the life of many a practitioner who finds the routine work of general practice monotonous.

HOME-GROWN CHEESE.

SAVE in a subsidiary way cheese does not play the substantial part which it deserves as a food among many classes of the community in this country, perhaps for the reason that reliance cannot always be placed on its quality. It is encouraging, therefore, to find that at a meeting of the English Cheddar Cheese-makers' Federation, which was held in the Town Hall, Highbridge (Somerset), on June 21st, the Duke of Somerset, the president, entered a plea for a wider interest among farmers in the production of good cheese with a view to successful competition with colonial products and the enlistment of the sympathy of the Government in promoting the prosperity of the industry. As arable land was increasingly turned into pasture, and more milk was being produced, something had to be done with the surplus supply, especially to retain its valuable vitamin content. At the present time, he said, there was an enormous quantity of imported and factory-made cheese sold as "Cheddar," and some system of standardising and stamping cheeses should be employed in order that the public might know what they were buying. Other speakers emphasised the importance of grading cheeses, and Mr. C. Harden, of Bridgwater, submitted a resolution urging the prohibition of the import of machine-skimmed condensed milk, admittedly unfit for infants' food, which amounted last year to 230,400,000 tins, an increase of 17,000,000 over the previous year. Mr. John Day, of East Pennard, a producer of tuberculin-tested milk, seconded the resolution, which was carried with acclamation.

AN UNUSUAL CASE OF FOREIGN BODY.

To the Editor of THE LANCET.

SIR,—A few days ago I was stopped on the road by an old man of 87 who said that while he was trimming a hedge on the previous day something had got into his eye, and would I please pull it out? On looking at the eye in an indifferent light I was surprised to see that the outer side of the conjunctiva appeared black. In a better light I removed a piece of smooth and stiff leaf which was neatly applied to the eye and large enough almost to obscure the conjunctiva on the outer side of the eye. The fact that the old fellow calmly put up with it for 24 hours and would not then have troubled unless he had chanced to meet me seems extraordinary.—I am, Sir, yours faithfully,

Clevedon, June 25th, 1927. R. L. WASON, M.R.C.S.

WANTED—AN EXPLANATION.

To the Editor of THE LANCET.

SIR,—Some two years ago I had to open a bottle of mineral water without an opener, and got my first right finger badly cut across the nail ¼ inch below the top. It took about ten days to heal; the nail partly came off.

I have just now the fourth recurrence of the injury—all are alike. I notice across the nail of the right index-finger a white line which appears without any apparent cause. This gets ragged (¼ inch below top of nail), and the nail gradually splits and bends at the white line, and eventually breaks off, just as if the accident had recurred at the time.

This persistent phase of organic memory is rather puzzling to me; but no doubt some reader can elucidate it. I have the split nail just now, and the lesion is fully as great and troublesome as before.—I am, Sir, yours faithfully,

A. T. SCHOFIELD, M.D.

Ryde, Isle of Wight, June 25th, 1927.

Lady Jones Lecture

ON

NEW CONCEPTIONS IN THE PATHOGENESIS OF SCIATIC PAIN.

Delivered at the University of Liverpool on March 10th, 1927,

BY PROF. V. PUTTI,

ISTITUTO ORTOPEDICO RIZZOLI, BOLOGNA.

IN this lecture I want to unfold a subject which has attracted my attention for many years and which I consider of general interest. What practitioner, indeed, is not interested in the discovery of the causes and cure of a disease, whose predominant symptom is pain?

There is a Latin saying: *Divinum est sedare dolorem.* If pain implies physical suffering, this divine labour is entirely entrusted to the wisdom and humanity of the doctor. Is not our highest, noblest, and most difficult task the endeavour, within our limitations, to soothe, diminish, and occasionally to abolish physical pain? For mental pain, man is his own best physician. One of the great tragic poets, Alfred de Musset, has said: "L'homme est un apprenti, et la douleur est son maitre." But for all that, will-power, moral training, self-control—none of them suffice to banish physical pain. Who but the doctor can hope to attain success, and what practitioner is indifferent to the great warfare against pain?

For the past four years and more I have been studying the subject of the causation of sciatic pain. I have had the opportunity of studying this symptom with vast clinical material, with dissections, and, above all, with a very rich collection of radiographs. While I was in the midst of my investigations, publications by French and American authors appeared which threw much light on the subject, and which suggested to me new points for observation. It has, therefore, seemed to me useful to communicate to you now my results up to date.

Amongst painful diseases, sciatica occupies a foremost place by reason of its prevalence, its production by a great variety of conditions, the great disablement it may produce, and its tendency to relapse; all of which have long ago led to its recognition as one of the great scourges of humanity. It has been known as long as medicine has been studied, but it has only been recognised as a clinical entity since an Italian physician, Domenico Cotunio, gave a complete description of it, towards the middle of the eighteenth century. The ancients named it ischias, and "De Ischiade Nervosa" is the title of the book in which Domenico Cotunio gave its clinical picture. Hence it was long called Cotunio's disease. The name of this great Neapolitan practitioner should not be unfamiliar to you, for it is to him we owe the first accurate description of the fluid contained in the meninges, the cerebro-spinal fluid, or Cotunio's fluid. Cotunio was not only the first to isolate sciatica as a clinical entity, but he also made a distinction between anterior and posterior sciatica, a differentiation which is based on good anatomical grounds and still has considerable clinical value.

Since the time of Cotunio, chiefly through the efforts of neurologists, the symptomatology of sciatica has been increasingly well defined, and to-day we may say that we have the complete clinical picture, and the differential diagnosis is easy. The same cannot be said of the pathology, which remains obscure in many respects. Orthopædic surgeons began to occupy themselves with the subject of sciatica when it was found that in many cases it was associated with deformities, and often took origin from malformations and diseases of the skeleton. Charcot was one of the first to draw attention to the frequent association of sciatica with vertebral deformity, and Brissot first coined the term "sciatic scoliosis," that is to say lateral curvature due to sciatica.

I already denoted sciatica a *symptom*, and such, I think, it should be considered, at any rate from the clinical standpoint. It is only when the pain is due to direct involvement of the nerve by the pathological process that sciatica can be considered a primary disease, and this is rare. In the majority of cases sciatica is only a manifestation of diseases external to the nerve, or at any rate the nerve is only involved as part of a constitutional disease. It is well known that diabetes, syphilis, alcoholism, lead poisoning, and other general toxæmias may cause sciatica by inducing inflammatory and degenerative changes in the nerve. These are true forms of neuritis and can be classed as alcoholic, diabetic, syphilitic, and so on, from the disease primarily responsible. In other cases, the cause is local, and pain is due to compression or irritation of the nerve-trunk at some point or other in its course. Such causes are: tuberculosis, syphilis, vertebral tumours, pelvic and other tumours, as well as fractures. Such secondary sciatica may have an infinite variety of causes, but these have no special interest for us at the moment.

The most common type of sciatica is not of these. It appears and progresses without obvious cause, or, to use the Latin expression, *sine materia.* It is usually called "essential" or "idiopathic sciatica," two rather meaningless words, which were created to indicate our ignorance of the origin and nature of the morbid process. Essential sciatica is sometimes called rheumatic sciatica, because it frequently develops after chills and in individuals of rheumatic or gouty constitution. It thus forms part of the neuro-arthritic syndrome, to which so much attention was formerly paid.

NATURE AND PATHOLOGY OF SCIATIC NEURALGIAS.

But, as a matter of fact, the true nature and mechanism of production of these neuralgias remained in complete obscurity until a few years ago—witness the innumerable therapeutic measures which had been evolved for their treatment. The cause being unknown, attempts were made to treat the results. But it is obvious that symptomatic treatment inevitably yields only unreliable, or incomplete, results, and it may be said that up to the present day there has been no rational, radical cure of idiopathic sciatica.

As the researches of the past few years have thrown much light on the subject, let us consider for a moment our points of departure and of attainment.

As is well known, the nervous system is responsible for the function of sensation. In the absence of nerve-fibres, there is no feeling, and hence no pain. There arise in every organ and every part of the body simple sensory nerves and also sympathetic sensory fibres, which, by various routes and various relations, conduct impressions from the periphery to special receiving centres, and such impressions as reach the cerebral cortex are perceived there as sensations. Any irritation of these sensory fibres in any part of their course induces, through stimulation of the cerebral cortex, the sensation of pain. Thus the cause of the pain may have situations as diverse as the types of irritation.

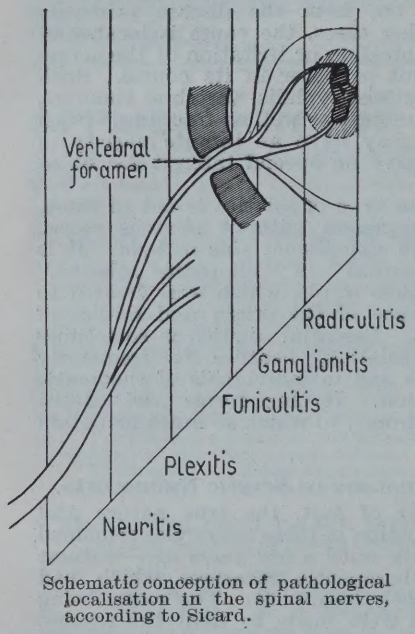
Localisation of Site of Irritation.

As regards diagnosing the level of irritation: if one considers the enormous length of the sensory tracts, one will realise how difficult it may be to localise the cause of pain. The irritation may occur in the peripheral nerve, in the plexus, in the spinal root, in the spinal cord, or in the brain. Pain, as such, has no localising sign. In quality there is no difference between pain originating in the spinal cord and in the peripheral nerve. There are certain gradations in quality, but these are too subtle and

variable to have distinctive value. For example, the pain of sympathetic origin, the so-called causalgia, has a burning, dry character. Root pains tend to be stabbing, crushing, or lightning pains, but as these phenomena are subjective and impossible to measure, we are dependent on the patient's description of them, which introduces an element of uncertainty. Conversely, it is well known that pain of central origin may be referred to the periphery, the classical example being the paræsthesia of amputated limbs. Alternatively, pain of peripheral origin may be referred to the centre.

For all this, there exist certain characters distinctive of certain levels of irritation, from which can be constructed a topographical classification of types of pain. From early times the term neuralgia has been reserved for pain arising in the peripheral nerve, that is the segment of nerve formed by the fusion of various roots in the plexus and extending to the periphery of the limb. Dejerine drew the clinical picture of *Radiculitis*, a form of pain resulting from disease of the nerve roots in the plexus. An even more careful analysis of clinical findings has enabled Sicard and his pupils to differentiate another type which is due to stimuli affecting the segment of nerve between the spinal root and the plexus, as it traverses the intervertebral canal. Sicard has named this part of the nerve trunk the funiculus, the little cord, and has called the pain syndrome, due to irritation at this level, funiculitis. Sicard and his pupil, Forestier, have attempted to give an anatomatical and clinical basis to the funicular syndrome, in contrast to the radicular syndrome of Dejerine (Fig. 1). Following the same lines to a somewhat theoretical conception, Sicard hopes in the future to attain to other topographical differentiations of pain, such as plexitis and ganglionitis—namely, the response to irritation of the limb plexus and of the spinal ganglion.

FIG. 1.



Schematic conception of pathological localisation in the spinal nerves, according to Sicard.

This is not the time to indulge in a critical examination of these new ideas of localisation of pain, but the most important result of these researches is the emergence of a new factor in the causation of neuralgia—that is to say, the vertebral element, or to be more general, the influence of the skeleton. The idea is not new, indeed, that a nerve may be irritated in the canal or foramen which it traverses. Long ago it was recognised that many types of trigeminal neuralgia, facial, suprascapular and Arnold's occipital nerve neuralgia, as well as ulnar and radial, are the result of mechanical irritation of the nerve trunk by the bony foramina, or osteo-periosteal canals. Sicard has re-named these conditions also; he calls them "nevrodocitis" derived from two Greek words: Neuron=nerve; and the verb Dekon=to contain. Nevrodocitis, therefore, indicates nerve pain due to stimulation of the nerve by the bony foramen or canal which contains it. We shall frequently make use of this term, which is descriptive and comprehensive.

VERTEBRAL AND PELVIC FACTORS IN SCIATICA.

As regards the pathology of sciatica, the importance of vertebral and pelvic factors was pointed out some years ago by an American orthopaedic surgeon, Goldthwait, of Boston. Goldthwait was the first to investigate the problem from its anatomical and mechanical aspects, and his work gave inspiration to a series of researches, which have thrown great light upon the matter. He was also the first to draw attention to the frequency of certain congenital anomalies of the spinal column, such as sacralisation of the fifth lumbar vertebra, and variations in the posterior articulations, while he pointed to the possible connexion between these abnormalities and sciatic pain. Goldthwait's views, after they had been defined and extended by other workers, became so popular that in a short time the subject of sacralisation of the fifth lumbar, and its association with sciatica, took a prominent place in medical literature. This was natural enough, for the desire to find an anatomic basis for sciatica and the actual frequency of morphological variations of the fifth lumbar vertebra naturally led to acceptance of Goldthwait's ideas and the recognition of the syndrome, which French authors have recently designated painful sacralisation of the fifth lumbar vertebra. The fifth lumbar vertebra is the foundation-stone of the vertebral column, and it is also much subject to congenital variations, because it is intermediate in position between two segments, the lumbar and the sacral, and has no fixed character. Thus, it is not uncommonly seen to resemble a sacral more than a lumbar vertebra. Its transverse processes may be so wide and deep that they exactly resemble the alae of the sacrum, and in extreme cases it is impossible to distinguish the fifth lumbar from the first sacral. The anomaly may be symmetrical or unilateral.

What connexion is there between the presence of these abnormalities and the development of sciatica? The connexion can easily be divined. In the intervertebral foramen, between the fifth lumbar and the first sacral, runs the fifth root of the lumbo-sacral plexus, a root which is the principal constituent of the sciatic nerve. If the transverse process of the fifth lumbar is wider and deeper, as in these cases of so-called sacralisation, then the lumen of the canal is narrowed and lengthened, and the fifth root may be irritated or compressed as it runs through the canal. Anatomical and radiological studies have demonstrated that sacralisation of the fifth lumbar occurs far more frequently than was formerly recognised. This discovery suggested for a time that the true cause of sciatica had been finally discovered. Some surgeons were induced by this discovery to treat sciatica by removal of the fifth lumbar transverse processes. They expected that, as soon as the process was removed and the canal thereby enlarged, the nerve would have a free course and the pain be cured. But unfortunately results have not always corresponded to their expectations, and criticism has now overturned the elaborate and somewhat theoretical edifice, erected on the base of lumbar sacralisation. It cannot be denied that sacralisation may sometimes be the cause of sciatica, but, on the other hand, the anomaly is frequently found to be present without any associated symptoms, referable to the lumbo-sacral plexus. It must also be borne in mind that the fourth lumbar contributes to the formation of the plexus, and it is often possible to demonstrate that the pain is due to involvement of this root and not of the fifth, which alone could be affected by sacralisation. Finally, if we consider the close relation existing between the development of the vertebral column and of the spinal cord in the embryo, we should expect that with reduction of the intervertebral foramen would be associated a smaller nerve-root, so eliminating the probability of compression. For the above reasons, and others, opinion now is in favour of considering lumbar sacralisation

as one, but by no means the most frequent or severe, of the causes of sciatica.

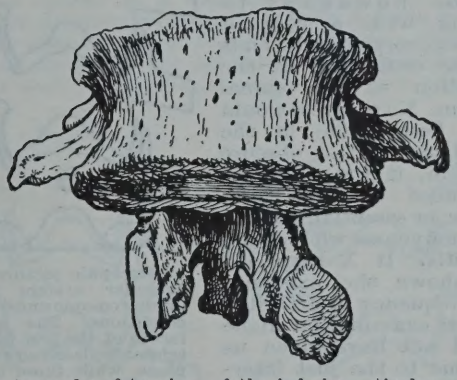
In view of the intimate relation of the roots of the sciatic nerve to the sacro-iliac synchondrosis, it has been stated that peculiarities and diseases of this joint may cause sciatica. This hypothesis lacks anatomical or clinical support; indeed, the recent investigations of Danforth and Wilson seem to exclude it.

ANATOMY OF LUMBAR SPINE IN RELATION TO SCIATICA.

For all this, we must not lose sight of the fact that the study of cases of sciatica shows one constant factor—namely, the association of the pain with anatomical alterations, or functional disturbance of the lumbar spine.

We referred previously to the name rheumatic sciatica, and it is common to find it occurring in individuals with various other rheumatic manifestations, more especially spinal rheumatism. It is common, in taking the history of a case of sciatica, to learn that the attack was preceded by repeated bouts of lumbago—that is, of pain in the lumbar region, which is now recognised as one of the manifestations of rheumatism. Occasionally sciatica comes on suddenly and violently after a quick stooping movement, such as the lifting of a load from the ground. The patient, as he bends, or rises, feels sudden sharp pain in the lumbar spine, which shoots down the course of the sciatic nerve and causes immediate rigidity of the back. This is the usual mechanism of the so-called traumatic lumbago, which results from torsion of the lumbar

FIG. 2.



Anomaly of tropism of the inferior articular facets of a lumbar vertebra.

articulations, and almost always causes sciatica. Cases of Pott's disease, involving the lumbar vertebræ, are often tormented with violent sciatic pain. In them the sciatica is secondary, but its existence demonstrates the close connexion between a vertebral lesion and sciatica.

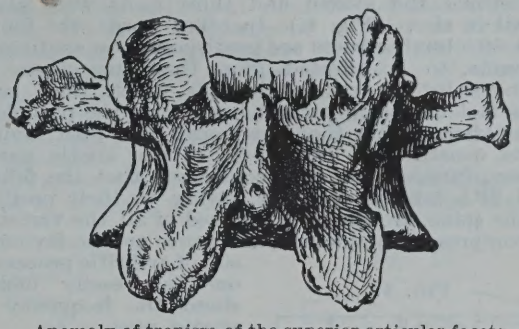
Many neuralgias of the trunk, upper limb, even of the head and face, take origin in some skeletal peculiarity, in fact, are the result of compression, or strain on nerves, or nerve roots, where they traverse bony canals. These are the ones comprised by Sicard under the name "nevrodocitis."

The peripheral nervous system is composed of bundles of nerve-fibres, which in escaping from the spinal canal must traverse a series of bony foramina at the sides of the vertebral column, the so-called intervertebral foramina. Hence the peripheral nerves are liable to be affected by the condition of the vertebral column, and more especially by the intervertebral foramina. In view of the important part these canals play in the pathology of neuralgia, it was desirable to study carefully their anatomical features and their relationship to the nerve roots. Anatomists and clinicians have shared the labour, and thanks to their investigations new light has been thrown on the pathogenesis of peripheral neuralgia.

What is the result of their studies? For the sake of clearness, we will first deal with the results of anatomical research, and later with clinical features. We shall restrict ourselves exclusively to the points which bear on the pathology of sciatica.

In general, the anatomy of the lumbar spine is familiar, but it seems worth while to emphasise

FIG. 3.



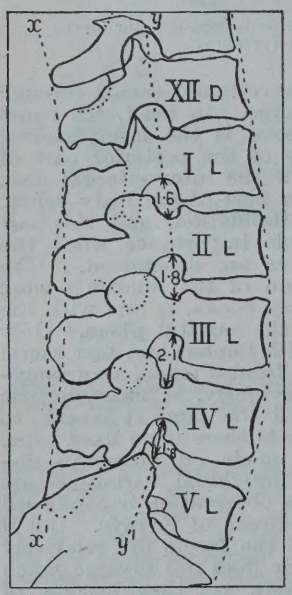
Anomaly of tropism of the superior articular facets of a lumbar vertebra.

the composition of the intervertebral canals through which the nerve roots emerge. In brief, the canal is formed as follows: Above is the intervertebral notch. In front is a little of the posterior part of the body above, a little of the intervertebral disc, and a little of the posterior part of the body below. Behind is the posterior articulation, and this last is a feature of considerable importance when the relations of the nerve roots are considered. The typical posterior articulation of the lumbar region, as it is depicted in anatomy books, is one with the articular facets placed in the sagittal plane. Only in the joint between the fifth lumbar and first sacral are the facets placed in the frontal plane, an arrangement which, as noted previously, is characteristic of the thoracic region. All the same it is safe to say that for the lumbar facets there is no fixed type. An investigation which I made on numerous dissections showed me that individual variations are very common indeed. This observation is confirmed by the study of many hundreds of X rays. But if variations in the angles of the facets are relatively unimportant when the angle does not diverge much from that considered normal, yet they become of great significance when they are of a severe degree of abnormality, and when they are unilateral only, a character by no means uncommon. I called attention to these peculiarities more than fifteen years ago in an article devoted to congenital deformities of the spine. I re-examined this material in my study of the pathology of sciatica and found it not uncommon to have one articulation in the sagittal plane, while its fellow was placed in the frontal plane. This arrangement may be met with in any of the lumbar vertebræ, but is most frequent in the articulations of the fifth lumbar with the first sacral. (Figs. 2 and 3.) We already noted that these joints are normally placed in the frontal plane, but it may happen that while one remains so, the other is exactly sagittal.

These anomalies may have a two-fold effect on the intervertebral foramen; firstly, they may alter its shape and reduce its capacity; secondarily, by altering the mechanics of the spinal column, they may induce a localised arthritis, which itself may irritate the nerve trunk. This effect may also be produced by all the inflammatory processes that have their seat in the vertebral articulations, and we know how frequently this occurs. The diseased joint, by its swelling and deformity, changes the shape and capacity of the foramen, thus irritating and compressing the nerve within it. Hence the neuralgia, or nevrodocitis.

Recent researches have shown that the intervertebral foramina are not all of the same size. The foramen between the fifth lumbar vertebra and the sacrum is always the smallest, that between the fourth and fifth vertebræ the next larger, and that between the fourth and third usually the next, although sometimes the second and third were about equal. Quite contrary to the size of the foramen or canal is the size of the nerve root enclosed. The fifth is always largest, the fourth next to the largest, and the third smaller as a rule, although sometimes the second and third roots were about equal in size. (Fig. 4.) In other words, the fourth and fifth lumbar roots are predisposed, on anatomical grounds, to be affected more than any others by changes in the canals through which they pass. This fact has an important bearing on the pathology of sciatica, seeing that the fourth and fifth lumbar roots constitute a large part of the sciatic nerve. When, furthermore, it is considered that the fourth and fifth lumbar vertebræ, owing to their position in the spine, are the most exposed of all the vertebræ to compression and strain, and hence are the favourite site of arthritic processes, one can easily understand the frequency of sciatic pain.

FIG. 4.



The difference in size of the various intervertebral foramina (from Bonniot).

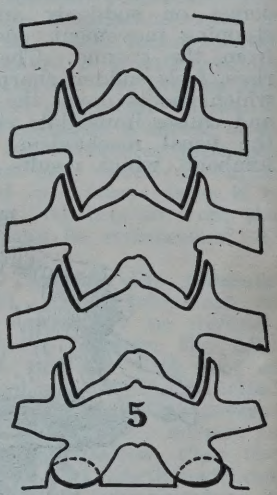
So much for the vertebral canal; but we must also consider its content, the funiculus. The most recent researches on this subject are those of Bonniot and Forestier. The conclusions of these two writers may be summarised as follows: The fourth and fifth lumbar nerves are those possessing the longest funicular portion of all those which constitute the lumbosacral plexus—namely, those with the longest course through intervertebral foramina. The funicular portion of the nerve, unlike the intraspinal portion, does not lie within the arachnoid, but is only clothed by dura mater, and is not bathed in cerebro-spinal fluid. Around the funiculus there is a very rich venous plexus, which is much influenced by mechanical conditions outside the funiculus. The absence of arachnoid, and therefore of a protective layer of fluid, exposes the funiculus to outside mechanical influences, such as do not affect the root, while the surrounding venous plexus puts it at the mercy of any congestion and stasis that may occur in the neighbourhood from many causes.

The intervertebral foramen for all these reasons constitutes a critical region, or as Sicard has happily named it, "carrefour de la douleur"—i.e., the crossroads of neuralgia. Any condition which modifies in the slightest degree the contents, or the container, at once induces a painful reaction, which is referred distally to the sciatic nerve.

Such conditions are discovered by X rays, or by clinical examination. The importance of X ray examination goes without saying, but it is necessary to be clear as to the interpretation to be placed on the X ray evidence. Up till now, many have paid more attention to alterations in the bodies and transverse processes than to modifications of the form and structure of the intervertebral canals. We have already referred to the fate of the so-called syndrome of painful sacralisation. The undue value given for a time to that syndrome distracted attention from phenomena of greater importance. It is undeniable that in certain cases the sciatica is caused by the sacralisation of the fifth lumbar, but the two phenomena are less frequently associated than has been asserted. The same may be said of all the forms of arthritis which affect chiefly the bodies of the vertebræ, and which are evidenced in X rays by bridges of bone uniting, more or less completely, the bodies themselves. This X ray picture corresponds to the well-known group of ankylosing disease, which pass under the name of arthritis deformans, ankylosing spondylitis, Bechterew's and Pierre Marie's diseases. Even in these it is possible that the morbid process, although mainly localised in the body of the vertebra, may influence the intervertebral canal, and thus indirectly irritate the nerve trunk, but it is certain that in the causation of sciatica the changes in the vertebral body are of minor importance compared to those in the articulations.

The abnormalities, deformities, and inflammations of these joints, and the alterations in form of the intervertebral foramen, have not been appreciated at their due value hitherto, because they are not easily recognised on a skiagram. But if one has available first-rate X rays, and above all, if one makes extensive use of stereoscopic X rays, no trained eye will fail to determine the form, size, relations, and structure of the foramina and also the articulations. I lay stress on this point, because nowadays in dealing with a case of sciatica everything depends on the estimation of the condition of the spinal column. No progress would have been made in the elucidation of this obscure problem, if X rays had not convinced us that idiopathic, or essential, sciatica is synonymous with spinal arthritis. If X rays had not shown the existence and frequency of arthritis, clinical examination alone would not have given us the clue to the just interpretation of the facts.

FIG. 5.



Radiographic picture of the articular system in the lumbar column under normal conditions. The articular facets of the first four vertebræ are placed on a sagittal plane, while those between the fifth lumbar and first sacral are in a frontal plane.

But, as I have said, to reveal the anatomical signs of vertebral arthritis, perfect radiograms and experienced examiners are indispensable. In many cases the alterations of the intervertebral articulations are not visible because the radiograms are imperfect, and often also vertebral arthritis is denied because its clinical manifestations have not been appreciated. The intervertebral articulations and foramina are two elements that are generally overlooked in the radiological examination of the spine, the attention of the examiner being commonly attracted to the condition of the bodies, the most conspicuous parts of the vertebræ. Almost always lateral views are neglected and stereoscopic radiograms are little used. It is not possible to judge rightly the conditions and proportions of the canals if lateral radiograms are not taken. And it is impossible to obtain a proper impression of the relations of the articular facets without a stereogram. However, the task is facilitated by the fact that it is the lumbar spine which is affected, the segment that lends itself best to a complete radiological study.

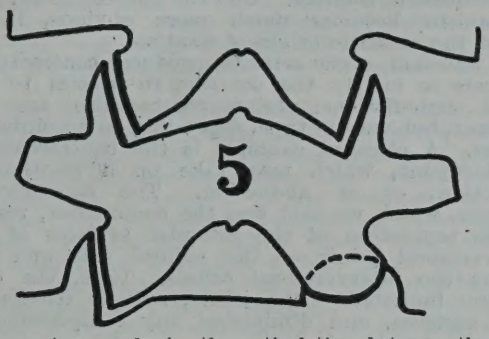
It would be very instructive to demonstrate the anomalies, deformities, and various forms of arthritis, which alter the intervertebral articulations and foramina, but to do so I should need the original

skiagrams, more particularly the stereoscopic ones, for the finer details are lost in lantern-slides.

ALTERATIONS IN INTERVERTEBRAL ARTICULATIONS AND FORAMINA.

I shall limit myself, however, to demonstrating those phenomena which can be found with greater

FIG. 6.

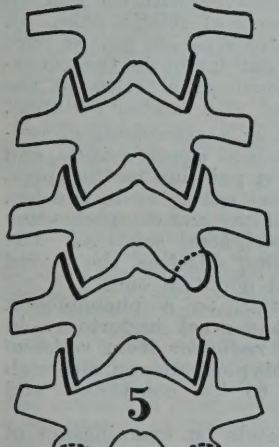


A frequent anomaly in the articulation between the fifth lumbar and first sacral; one articulation is in the frontal plane while the other is in the sagittal. (Anomaly of the articular tropism.)

frequency and ease on radiographic examination, and especially those that have the greatest clinical importance.

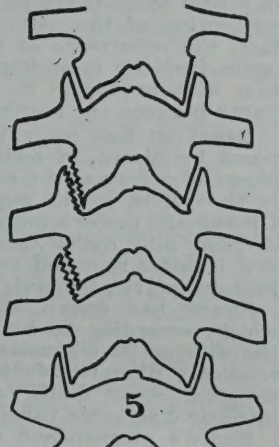
Fig. 5 demonstrates in a diagrammatic way what may be considered the normal radiographic aspect of the articular processes that unite the first four vertebræ, which, as it has been said, have their articular spaces in a sagittal plane. They appear upon the diagram as clear lines with definite borders and in almost perpendicular direction. This line does not appear in the articulation between the fifth lumbar and the sacrum, because it is not normally

FIG. 7.



Another example of anomaly of the articular tropism; the articulation on the right, between the third and fourth lumbar vertebræ, is on a frontal plane.

FIG. 8.



Schematic representation of the radiographic signs in lumbar arthritis (between second and third, third and fourth lumbar vertebræ), left side.

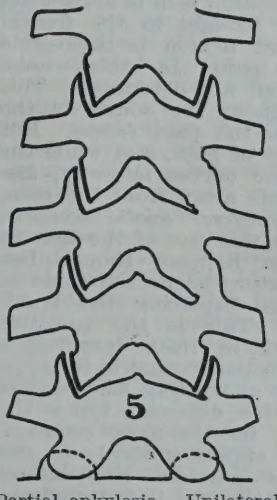
directed on a frontal plane. If the conditions which I have stated above are kept in mind it will not be difficult to discover anomalies or anatomical alterations of the lumbar articulations.

Fig. 6 illustrates an anomaly that frequently appears in the relationship between the fifth lumbar and the sacrum. One articulation preserves the normal position, while the other assumes the radiographic characteristics that belong to the first four lumbar vertebræ. The same anomaly may occur in the articular relations between the other vertebræ. (Fig. 7.) To this condition I have given the name of "anomaly of the articular tropism."

But that which interests us mostly is the proof of the phenomena which follow inflammatory processes of the articulations. They are in reality the same which radiograms demonstrate in every arthritis even though not vertebral. The articular surfaces instead of appearing smooth and parallel appear jagged and rough, as diagrammatically shown in Fig. 8. With perfect radiograms it is possible to determine the structural condition of the articular tissues. It is not infrequent to find a localised ankylosis in one or another of the articulations. This is represented on the radiogram by absence of one or more articular spaces. (See Fig. 9.) The radiographic aspect of a total ankylosis is very characteristic, as the joint space has completely disappeared. (Fig. 10.)

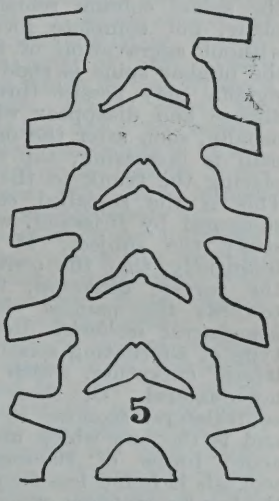
Nowadays the cause of sciatica is to be diagnosed more by a study of the X rays than of the clinical

FIG. 9.



Partial ankylosis. Unilateral (between second and third, third and fourth lumbar vertebræ).

FIG. 10.



Total ankylosis.

symptoms. This does not mean that one is to neglect investigation of the symptoms. Diagnosis, the constant preoccupation of the medical mind, is a conclusion drawn from a study of the facts which knowledge and experience enable us to perceive. The more numerous and objective the facts, the easier and safer the conclusion. But this judgment is born less of the bald assemblage of facts and scholastic classification of them, than of a reasoned analysis of their relation to one another, their logical interdependence. Longfellow has well said:—

> None but a clever dialectician
> Can hope to become a great physician.
> Logic makes an important part
> Of the mystery of the healing art,
> For without it how could you hope to show
> That nobody knows so much as you know?

CLINICAL MANIFESTATIONS OF SCIATICA.

Let us not, therefore, neglect the clinical manifestations of sciatica. Amongst the symptoms is a constant one that may well be called spinal. I mean the *rigidity of the lumbar spine*. Next to pain, this is the dominating feature of idiopathic sciatica. It is well known that there is no clear-cut clinical picture in this disease. Lasègue's sign—namely, the pain caused by expension of the knee with simultaneous flexion of the hip, is neither constant nor characteristic of idiopathic sciatica. Absence of the knee- and ankle-jerks, muscle atrophy, sensory changes, are all phenomena of value in certain cases, but cannot be called pathognomonic.

Even lumbar spasm cannot be correctly called a special symptom, for it exists in every case of irritation of the lumbar spine; nevertheless, it acquires great diagnostic value when it is associated with sciatic pain. It is absent in root sciatica and in all the secondary forms of sciatica. On the contrary, it is always present, or nearly always, in the rheumatic, arthritic type. We have repeated that this type is due to joint disease. Every joint responds to irritation by contractures of the muscles which control its movements. This contracture represents a *defensive reflex*—that is, a reflex designed to protect the joint from pain. The contracture produces this defence by immobilising the joint. The joint is thus fixed in an attitude which may be called protective, an attitude which relieves it of pain. As we said, this attitude has nothing characteristic of vertebral joints or of sciatica. It is found in every painful joint, and each joint has its own special protective attitude. The vertebral column is nothing but a congeries of joints, and as such it protects itself from pain by assuming characteristic attitudes. Scoliosis is the protective contracture of the vertebral articulations.

In the early stages, when sciatic pain is not severe, the spinal column remains straight in the frontal plane, but complete forward flexion is impossible without aggravation of the pain. In other words, the lumbar spine is rigid, but not deformed. This rigidity may persist throughout the course of the disease and disappear when the pain ceases. But usually, soon after the onset of pain, and while the pain is increasing, the spine curves laterally, displacing the trunk to the side away from the pain. This is the so-called *contralateral sciatic scoliosis*, so-named by Brissaud, who was one of the first to study the subject. It can happen, though less frequently, that the contracture bends the spine in the reverse direction, thus displacing the trunk towards the painful side. This is the so-called *homolateral scoliosis*. Remak, in 1890, described a type of alternating sciatic scoliosis—that is to say, a lateral curvature, which is alternately contra- and nomo-lateral. Of these three different types the contralateral scoliosis is by far the most common, and is the one which may appear suddenly in the acute forms of rheumatic sciatica. Homolateral scoliosis is found less frequently, and then usually in the less severe types of sciatica, and those which have a gradual onset. The alternating type is the rarest of the three. It begins as contralateral scoliosis and, in time, develops into the alternating form.

But why should these vertebral contractures and deformities be so diverse. Why in apparently identical cases, identical alike in duration and severity, should one show a contralateral scoliosis, another homolateral, and a third alternating? This is a clinical problem that appeared very difficult to solve. Its investigation is important, not only on theoretical, but also, and more particularly on practical grounds, because these deformities may be extremely severe in type, long in duration, and even persistent after the pain has disappeared. Hypotheses have been brought forward by men of authority such as Charcot, Gussenbauer, Hoffa, and Lorenz. But the explanations have seldom seemed convincing. To-day, thanks to the studies to which we have already referred, a new light has been thrown on the subject.

One thing is beyond dispute: that scoliosis, of whatever type, is due to *muscular contracture*, which is itself a reflex, induced by the pain with the object of diminishing the pain. Ask the patient and examine him, and you will soon be convinced of this fact. Try to correct and overcome the scoliosis, and you will find the patient protest, because the pain immediately becomes unbearable. If you ask the patient, he will tell you that the curvature came on spontaneously, and that he does not try to correct it, because that increases his pain. Thus the contracture and scoliosis have as their purpose the diminution of pain. How is this achieved? By what mechanism can these various contractures reduce pain? The commonly accepted explanation is that the attitude of the trunk, together with abduction and flexion of the affected limb, produces a relaxation of the sciatic nerve, and thus relieves the pain. But this hypothesis does not explain all the facts. Were this true, the scoliosis should be always of the same type, and all forms of sciatica should produce it, whereas we know it is characteristic of rheumatic sciatica. On the other hand, the mechanism becomes much more obvious, if we accept the arthritic origin of sciatica.

As was said, every arthritis produces contractures. Scoliosis is merely the contracture special to the spinal articulations. Joint contractures are not constant, but vary in type, depending on a number of factors. A classical example is the contracture of the hip-joint, which may take up a position of adduction, or of abduction. The contralateral scoliosis, which we said was the commonest, results in the separation of the articular surfaces of the intervertebral joints on the painful side and also widens the intervertebral canals. Thus, the contracture immobilises the joints, reduces friction of their surfaces, and diminishes any compression of the nerve-trunks.

Homolateral scoliosis relaxes the joints and makes the nerve cords relax on the painful side. In all the cases of alternating scoliosis that we have been able to examine by X rays, we have found a bilateral arthritis of the joints between the fifth lumbar and the sacrum. We therefore think that the scoliosis is alternating because the arthritis is bilateral. The change of attitude is the result of the need felt by the patient to rest the joints first of one side and then the other. In short, this is the explanation we give of that most important symptom of idiopathic sciatica, the scoliosis. Thus considered, the scoliosis no longer represents an isolated phenomenon, but a manifestation logically to be expected, with numerous analogies and an anatomic basis. Indeed, the vertebral arthritis, the essential cause of the scoliosis, is no abstract conception but a fact demonstrated by X rays. This conception of the mechanism of sciatic scoliosis agrees, moreover, with the modern conception of the pathogenesis of sciatic pain. In fact, the occurrence of sciatic scoliosis proves once again that the most important factor in the causation of neurodocitis is a localised arthritis of the joints between the fourth and fifth lumbar vertebræ.

Based on this conception is a classification, proposed by Sicard, of sciatica into *upper*, *middle*, and *lower*, according as the seat of pain lies in the spine, in the pelvis, in the popliteal space, or in the leg. I personally prefer a more definite and comprehensive division into *central* and *peripheral* sciatica. The first includes root and vertebral sciaticas, the second includes pelvic, femoral, and popliteal ones.

Sicard has drawn attention to a phenomenon which, according to him, has great importance in the differential diagnosis of *radicular* from *vertebral* sciatica. We must refer to this phenomenon, although we feel some doubt as to its constancy and intrinsic diagnostic value.

Sicard's phenomenon depends on examination of the cerebro-spinal fluid. In *root sciatica* there is said to be a lymphocytosis; in *funiculitis* an increase in the albumin content, without lymphocytosis, a state of the fluid which Sicard and Foix have called cell-albumin dissociation.

The increase of albumin, which is supposed to be peculiar to funiculitis, is due, according to Sicard, to the obstruction to the venous circulation by inflammation and compression in the canal. The control experiments which we have carried out on numerous patients have not led us to any definite conclusion in the matter. Beyond the symptoms to which we have referred, idiopathic sciatica shows others of an eminently neurological character. But their diagnostic importance is relative. Naturally an inflammatory reaction in a mixed nerve like the sciatic induces, besides pain, symptoms of trophic,

sensory, motor, reflex, and sympathetic nature. Often there is general reduction of the muscles of the whole limb, more particularly of the thigh and leg. In some severe cases one finds paresis or paralysis of the external popliteal, but tests have never shown the electrical reactions of degeneration. More important is the condition of the reflexes. The ankle-jerk is the one most often affected. Frequently it is abolished, nor is it rare to find it diminished. We have seen cases in which, many years after the disappearance of every symptom of sciatica, the ankle-jerk was still absent. The knee-jerk also varies, and its disappearance is by no means rare.

THE SCIENTIFIC TREATMENT OF SCIATICA.

This seems to me the moment to answer a question which I imagine some of you are longing to put to me: What influence have these new conceptions of the pathology of sciatica on the treatment of the pain itself? If a treatment initiated on pathological grounds produces the desired effect, that fact of itself constitutes the most certain proof that the cause of the disease has been correctly ascertained. The results which I have obtained in a large number of cases of idiopathic sciatica by applying treatment based on the conviction that it is the consequence of spinal arthritis, demonstrate, in my opinion, that my conviction is correct.

It is unnecessary to enumerate the therapeutic measures which have been applied in sciatica. These measures were almost exclusively symptomatic. The cause being unknown, an attempt was made to treat the results, and efforts were made to overcome the pain with all measures, chemical, physical, mechanical, and surgical, at the disposal of the profession.

Once convinced that idiopathic sciatica takes origin in spinal arthritis, we followed out in its treatment the two fundamental principles of treatment for any non-specific arthritis—namely, *active hyperæmia* and *immobilisation*. Active hyperæmia, obtained by the action of heat on the part, causes vasodilatation in the neighbourhood of the joint and hence an active interchange of fluids, which by self-immunisation has a curative effect on the arthritis. Immobilisation rests the joints and relieves it from mechanical irritation.

The technique of this treatment is briefly as follows:—

In the acute stage the patient is rigorously confined to bed. When the diagnosis has been confirmed, active hyperæmia is begun, which consists in a daily hot-air bath. The bath is given by one of the numerous forms of apparatus that have been designed for this purpose. We greatly prefer Bier's apparatus, which consists of a wooden box, adapted to contain the part of the body which it is desired to expose to the action of heat. Into this box is driven a current of hot air produced by a spirit lamp. With Bier's apparatus it is easy to attain the maximum temperature which the body will stand. If the general condition of the patient allows, the bath will be given daily for 30 to 40 minutes. In the first few days the temperature will rise to about 90° C., later to a maximum of 120° to 125°. The hot bath will be followed by general massage. In the great majority of cases one finds, after the first few baths, an aggravation of the pain, quickly followed by decisive improvement.

The moment the patient is fit to stand for a time without pain the second stage of treatment is initiated—namely, immobilisation. This is obtained by means of a plaster jacket. I cannot stop to describe the technique of the making of this jacket. A few general rules must suffice:—

1. The jacket must give fixation to the pelvis and trunk, except the shoulders.

2. It must only immobilise, not attempt to correct. Even if severe scoliosis is present it must not be interfered with.

3. The jacket must never be left on any longer than is necessary for the setting of the plaster, which is about 30 minutes.

Allow me to lay stress on the point that the jacket must immobilise and not attempt to correct. Its only purpose is to rest the inflamed joints. We said before that the spinal contracture represents the patient's own method of reducing pain. To correct the contracture is to exacerbate the pain. The contracture must disappear spontaneously as the result of immobilisation. Experience has shown that leaving the corset on causes within 24 hours a very severe spasm of pain. The sciatica case cannot endure any compulsory position for more than a few moments. Pain compels him to change the position of his spine every few minutes. For this reason the corset must be removed as soon as it is finished. It is to be worn daily for increasing periods, until the patient is used to it. This will be within a few days. Usually by the end of a week the patient is able to tolerate the corset continuously. Meanwhile the hyperæmia treatment is continued. This treatment is usually completed in 18 to 20 baths. On the contrary, it is impossible to fix the end of the immobilisation period. Usually, after two or three months, the plaster jacket can be replaced by a celluloid corset. In mild cases of spinal sciatica immobilisation will be continued for not less than six months; in more serious cases the jacket may need to be worn for more than a year.

This is not the time to dwell at length on statistics of the results of this treatment. Long experience has shown me that it rests on a good foundation, because the results are good in the majority of cases. There are, indeed, very severe cases which do not improve with conservative treatment. Some years ago Sicard advised resort in these cases to surgical measures—that is, laminectomy. According to Sicard, laminectomy—namely, removal of the laminæ of the fifth, fourth, and sometimes the third lumbar vertebræ—would result in decompression of the funiculi. In some cases operated on by Robineau, Sicard observed that the dura mater was irregular with scar tissue, which he thought might have some bearing on the causation of sciatica. Sicard regards the results of laminectomy as most favourable.

I have only encountered a single case of arthritic sciatica which resisted all conservative treatment, and in which I felt compelled to resort to surgery. The case was that of a man of 52, who for more than 30 years suffered from periodic attacks of sciatica, and who for some months has been unable to assume the upright position. There was severe lumbar contracture, which had produced a rigid, contralateral scoliosis. The X ray showed advanced pathological changes in the bodies and articulations of the fourth and fifth lumbar vertebræ. In this case I did not limit myself to carrying out a laminectomy, because it seemed to me an operation insufficient to relieve compression of the funiculi. The vertebral laminæ take no part in the formation of the intervertebral foramina. In order to decompress the funiculi it is necessary to open the bony canal, which can only be done by resecting the posterior articulations, which is what I did in my case. After removing the laminæ of the fifth, fourth, and third lumbar vertebræ, I resected the posterior articulations which unite the fourth to the fifth lumbar, and it to the sacrum. Thus I succeeded in completely exposing the fourth and fifth lumbar nerves on both sides. I did not see any macroscopic changes in the meninges, in the roots, or in the funiculi. Complete success resulted. In a few days the patient was free from all pain; at the end of a month he could get up and walk without difficulty in a plaster jacket. The improvement is maintained more than three years after the operation. This result shows that even for the most severe cases of sciatica there exists a cure, and it also demonstrates once again that the explanation of the pathology of sciatica which has been put forward in this lecture is a rational one.

CONCLUSIONS.

Sciatic pain is symptomatic of vertebral arthritis excepting in those rare cases in which it is a symptom of a neuritis of specific nature. Sciatica is a neuralgia caused by pathological conditions of the intervertebral

foramina and especially of the intervertebral articulations. In other words, sciatica is a symptom of neurodocitis and lumbarthritis.

The terms rheumatic sciatica and idiopathic sciatica should be substituted by the more precise and adequate one of *arthritic* or *vertebral sciatica.*

To treat the sciatica it is necessary to treat the arthritis.

The treatment of vertebral arthritis is based upon the same principles as the treatment of all other arthritis of non-specific origin, therefore active hyperæmia and immobilisation. When these two methods are inefficacious it will be necessary to resort to a resection of the diseased articulations.

An Address
ON
VISCEROPTOSIS.

A Contribution to the Discussion at the Meeting of the Association of Surgeons at Glasgow on May 5th, 1927.

BY A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

(*Concluded from p. 4.*)

SYMPTOMS.

THE clinical importance of cases of visceroptosis lies in the fact that their symptoms so closely resemble those of localised organic lesions, the treatment of which is almost wholly surgical. It is the one condition which causes difficulty in the diagnosis of abdominal disease. As a general rule, the mimicry is incomplete, and it is not a difficult matter to say that a patient is suffering from ptosis, but it is often extremely difficult to determine whether there is in addition some organic lesion. In the earlier stages the symptoms are frequently localised to one viscus, so that it is convenient to consider them under the heading of the lesions which they simulate. Later in life, or in the more advanced cases, the changes become more widespread and the symptoms correspondingly generalised. The actual symptoms of the individual groups have been so frequently discussed that it is unnecessary to consider them again in detail. The points of distinction upon which stress must be laid are that the condition is much more common in women, and that in them there will have been the onset of abdominal symptoms soon after puberty, and while they are yet at school. From this time the patient is rarely free from trouble, the characteristic periodicity of a chronic gastric or duodenal ulcer being absent; as she often expresses it, she "has always suffered from a delicate stomach and has had to take great care in her diet and life." The more acute attacks will usually only persist for a few days, but the intervals of comparative freedom will also be short. There will thus often have been a history of many years duration during which time symptoms have progressed little, if at all, and this will at once give a clue to the nature of the pathological lesion, for had there been any organic disease of the stomach, gall-bladder or appendix, it is certain that the organic condition would have progressed and the symptoms would have become correspondingly more severe. The pain will differ in its site and characters according to whether the symptoms resemble more closely a lesion of the stomach, gall-bladder, appendix, or kidney, but in general it consists of a dull, aching pain which is widely spread over the abdomen, in the gastric cases may be worse immediately after food, is of a dragging, heavy character, is increased when the patient is tired or worried, and is considerably relieved by lying down. In addition there are often attacks of more severe and almost colicky pain which are probably due to kinking of the stomach or large intestine. In the case of a mobile kidney the kinking of the ureter may cause colicky attacks very similar to those of a calculus.

Vomiting is a frequent symptom, and in the gastric cases is much more common and severe than is usually found with an organic lesion, probably owing to a gastritis secondary to the atony and prolapse. The vomiting does not completely relieve the pain, although it occurs at the height of the pain after each meal. In the gastric type of case, hæmatemesis is very frequent and is often severe, again because there is a secondary gastritis with the presence of erosions. The appetite is poor for the same reason, and in nearly every case the patient is constipated. In a certain group of cases there is irritation of, rather than stagnation in, the colon with the presence of colic and diarrhœa. Many cases of mucous colitis have, in fact, advanced general ptosis. Uterine prolapse is commonly present. On examination these patients are always tall, thin, energetic, and often, indeed, irritable people showing all the body characters of virginal ptosis. The constriction of the upper abdomen both laterally and anteroposteriorly is usually very evident. Dilatation of the stomach and cæcum is made evident by splashing and gurgling on palpation, and if the abdominal wall is very weak peristalsis may even be visible, but is never so strong and forcible as with a mechanical obstruction. The right kidney is generally mobile. Hyperæsthesia corresponding either to the stomach or cæcal areas is very common, and since such a condition is rarely if ever found with a chronic gastric ulcer, this sign is often a useful point in the differential diagnosis. Deep tenderness, if present at all, will be found over the whole area of the viscus —e.g., the stomach—and is not localised to a small mid-epigastric area as with a chronic gastric ulcer. In the variety appearing in middle-aged men there will, of course, not be the characteristic body changes, and often the only physical signs which are found are the presence of hyperæsthesia in the gastric area and a diffuse rather than a localised deep tenderness.

The test-meal may be very confusing, for not uncommonly these patients have a high degree of acidity. The highest free acid which I have ever seen was 0·35 per cent., and was found in a patient who had only visceroptosis. This fact should always be kept in mind, for if the symptoms resemble a pyloric ulcer the presence of such a high acidity may seem to confirm the diagnosis. In the more acute cases in young women the acidity tends to be low, and in the atonic type found in middle-aged men the absence of free HCl is very common owing to the presence of gastritis, thus increasing the difficulty in the distinction of this type from carcinoma of the stomach.

X ray examination is of very great value. On the screen it will be found not only that the stomach and colon are much lower than normal, but in nearly every case the ptosis is associated with atony, and hence there is a very marked difference in the position of the viscera when the patient is erect or lying down. The stomach, the cæcum, and often portions of the colon, are exceptionally dilated, and there is very considerable delay in the passage of the opaque meal. Kinking and delay in the passage owing to the accessory bands and adhesions is, as Jordan has demonstrated, often evident. Local areas of spasm maintained for a relatively long time, are not uncommon in both stomach and colon, the latter being most often seen in the acquired varieties at or about middle age (Fig. 3). Of equal value with the positive findings is the absence of any indication of the organic disease which is so closely simulated by the symptoms. In the difficult cases in women, for instance, there is no evidence of a penetrating ulcer of the lesser curve or of a duodenal ulcer, and in many cases the appendix is found to fill normally, so that the diagnosis of chronic appendicitis is unlikely. It must, of course, be remembered that ptosis in itself may in people with a good postural tone give rise to no symptoms, and therefore its mere presence, as demonstrated by X ray investigation, does not exclude the possibility

of some other disease. Especially must this be remembered when the symptoms are those of chronic cholelithasis or chronic cholecystitis, and it may be necessary with the clinical picture of this disease to carry out a special investigation after the administration of tetraiodophenolphthalein. It is in the acquired cases in men where the symptoms are those of early carcinoma of the stomach that difficulty may specially arise, for in such early cases the X ray evidence may be very doubtful, and this is also true with the small posterior chronic ulcers. Hence, even with the most careful investigation, it is not always possible to avoid operating for a supposed ulcer or early carcinoma, only to find that the symptoms are due to ptosis.

TREATMENT.

There is no condition in surgery which has led to so many fallacious and useless operations—fallacious because the operation has been so frequently carried out in the belief that some organic lesion is present, and useless because only too frequently attention has been directed wholly to one of the many pathological changes, and a form of treatment has been lauded and widely carried out in the belief that the overcoming of that one pathological change would lead to a complete cure of all symptoms. A wider appreciation of the fact that the symptoms are due to a combination of a congenital error with an acquired loss of postural muscular tone, will make it evident that attention must at first be wholly directed to medical methods of overcoming the acquired disability. As far as I am aware, practically no case can be said to have died directly from the effects of ptosis alone. It has been frequently held out as an indication for operation that virginal ptosis is the direct cause of many organic lesions, and it has been my aim to show that my own experience does not support this view. It is becoming to me, at any rate, more and more evident that ptosis is not the cause of gastric ulcer, of gall-stones, or carcinoma, or of chronic appendicitis, although in rare cases it may be complicated with any of these conditions. As far as my own experience goes in a follow-up department which has been in existence for a period of eight years, there is a tendency for the symptoms of virginal ptosis to die out as the patient gets older, but my experience as yet is insufficient to be dogmatic on this point. I think the majority of surgeons with wide abdominal experience will agree that it is very seldom necessary to have to give treatment to unoperated cases of virginal ptosis in patients of over 60, nor—if one excludes the cases of Hirschsprung's disease and volvulus, which should very doubtfully be included with ptosis—is there any indication that these patients die as a direct cause of their disease. On the other hand, we have all of us had only too wide an experience of the miserable subjects of extensive forms of operation. There is perhaps no condition which is so distressing to a patient as the severe abdominal symptoms and upset in the progress of their life as the after-results of unsatisfactory forms of treatment, such as is seen after wide fixation, lateral anastomosis, or resections of the colon, and it must always be remembered that these operations, however carefully performed, not only carry with them a direct immediate mortality, but there is a secondary mortality after they have been initiated. It may therefore be said that in no case of visceroptosis should operative treatment ever be considered until medical measures have been thoroughly and conscientiously carried out. Unfortunately, in but few of these patients is it possible to carry out the ideal treatment. If we could remove them from the disabilities of their work and could transplant them, while still young, to a healthy country life and air with congenial outdoor work, or if we could order the poorer and overworked patients a prescription of £500 a year, a cure would probably soon follow. These people are unsuited to the strain of civilised life, but the difficulty is that few, if any, of them are able to be removed from their surroundings. Attempts must therefore be made to improve their symptoms by medical measures which aim at improving their diet, at overcoming their abnormal bowel action, at increasing their postural tone, and at improving their mental outlook on life. By such means a very great deal can be accomplished, although as long as they continue under the influences which have produced their symptoms their abdomens will always be their weak points, and therefore they can rarely be regarded as completely cured.

Limitations of space will prevent a detailed consideration of the various surgical measures which have been advocated, but it is important to consider the indications for operative interference. Even with the greatest care in making a diagnosis we shall still, for a time, operate upon some patients in the belief that an organic lesion is present. Apart, however, from these accidental cases, the indications for operation are:—

1. The patient must have had a careful and complete course of medical treatment. Not only must this have failed to give relief, but the patient must feel that under her conditions life is intolerable, and that she would be willing to change a condition of discomfort which carried no risk of life for a surgical adventure which may succeed in giving her relief, but at the same time does give a definite small percentage of vital risk.

2. Operation should only be performed if the symptoms are definitely localised to one viscus. If they are widely spread over the whole abdominal contents, no operative measure is likely to give any lasting relief. On the other hand, we are all conversant with cases where the symptoms are localised to one organ where an almost complete symptomatic cure can be brought about by operative interference. For instance, a patient who has a mobile kidney with kinking of the ureter can usually be cured by a well-performed nephropexy, and in the same way operations directed to the stomach or cæcum may give a great deal of relief. As regards the actual operative technique, any operation upon one viscus should first of all aim at the complete and free division of all the accessory membranes and bands, but it must be remembered that such bands rarely if ever cause mechanical obstruction, although the gut appears to be tied down by a Lane's kink or a Jackson's membrane. It is very seldom indeed that one ever meets with a definite hypertrophy of the gut proximal to such a band, and it is this fact which must ever be kept in mind, for it is the belief that such a mechanical obstruction exists which has led to the wide introduction of operative treatment, and especially to the use of lateral anastomosis and partial or complete resection. Nevertheless, the kinking of such bands may possibly give rise to spasmodic contractions, and hence they should be freely divided before any form of fixation is carried out. Some of my cases have been very greatly relieved by gastrocolopexy. This operation I have carried out in 31 instances only, for it has only been performed in those cases where medical treatment has failed, and where the symptoms have been localised entirely to the stomach. Under such conditions the relief is often very considerable, but even then it must be combined with careful after-medical treatment. Of the various methods which have been introduced, I much prefer the Coffey operation as not only giving a firmer and wider fixation but as interfering less than any of the other operations with the normal action of the stomach. Cæcopexy, in a similar way, is an operation of limited application. I have only performed it eight times in my series, and since these cases have been most carefully selected a considerable relief has followed. The wide introduction of the Wilms operation or its modification as advocated by Waugh is, however, likely to lead to disastrous results. There is not the slightest evidence that the whole series of changes and symptoms is dependent upon any primary change in the cæcum, and I have only too frequently met with cases where this operation has been inadvisedly performed and has led to

no relief, but rather to an exacerbation of the symptoms.

In the use of lateral anastomosis the same care has to be exercised. It is remarkable in reading the literature on the performance of duodeno-jejunostomy for duodenal ileus to observe what very great difference of opinion there is as to its value, and I cannot help but feel that it has been performed in many cases where it is unnecessary. In my own series there have only been five cases of very definite duodenal ileus where this operation has been performed. In two of them practically a complete cure of all symptoms has followed, although the patients have still shown all the characters of virginal ptosis. In the other three, relief has been less complete, and medical measures still have to be carried out. For the dilated and atonic stomach, the use of gastro-enterostomy has been generally found to be so unsatisfactory that it may be said to have been abandoned, and I think there are very few surgeons to-day who will advocate its use. Even for the dilated and atonic colon these operations of lateral or end-to-side anastomosis are beginning to fall into disuse. So many cases have been reported, and even more have been known, where the condition of the patient has only been made worse, that it has not been widely adopted. Only too often the loop or excluded portion of the intestine continues to fill up by a retrograde passage of the contents, so that the patient's life is made more miserable, and indeed not infrequently subsequent operations have to be performed simply to overcome the added disability of the lateral anastomosis. In a few cases where the atony and dilatation is limited to the cæcum some relief may be obtained by these measures, and especially if they are combined with cæcostomy or appendicostomy, but such cases are relatively few.

Resection of gut also has a much narrower scope than was at one time believed. If the evidence could be accepted that the primary change was in the large intestine, and that the alterations in the small intestine and stomach only followed a prolonged dilatation and stasis in this part of the gut, it would be very tempting to remove a portion or the whole of the large intestine in the hope of bringing about a complete cure, and it was on such an assumption that Lane's operation became at one time extremely popular, but in the experience of most surgeons the results have not come up to our expectations. In the hands of the majority of surgeons the operation can certainly not be described as one of only moderate severity, but is one carrying with it a very high mortality. Nor do the after-results give complete satisfaction; in only too many cases the small intestine becomes atonic and dilated, and the patients complain of symptoms often more marked than those before the resection. Either frequent diarrhœa or a steadily progressive intestinal obstruction, sometimes of a mechanical nature, are by no means uncommon complications. Partial colectomies, either with removal of the cæcum or ascending colon in long-standing cases, sometimes give considerable relief, but here, again, the operation not only carries with it an immediate danger to life, but there is a risk of subsequent obstruction by adhesions and the recurrence of the original symptoms by spread of the atonic condition to the remaining portion of the large gut. As with the other forms of operative treatment, a partial colectomy therefore should be reserved for these cases in which the symptoms and pathological changes are almost wholly limited to a small portion of the intestine. It has been of some interest to me in analysing my own cases to find that the greater number of those in whom I have had to perform anastomoses or partial and complete colectomies have been patients who have already had a large number of previous operations elsewhere, so that interference of this sort has in part, at any rate, been necessary to overcome the effects of operative treatment as much as for the original disease.

The fact that the pain is spasmodic in character is suggestive that it may be due to overaction of the sympathetic nerves. The satisfactory results obtained by Hunter and Royle in division of the sympathetic to overcome spastic diaplegia, by Leriche and Benisty in the treatment of Raynaud's disease, and other spasmodic conditions of the artery by division of the sympathetic supply, and by the use of Jonesco's method of removing the stellate ganglion or other portions of the cervical sympathetic in the treatment of angina pectoris, has often led me to think that relief might be obtained by the introduction of similar methods in the treatment of visceroptotic pain. Such methods would, however, be surrounded by considerable difficulty. Anatomically, it would not be a matter of great difficulty to expose the sympathetic cords in the upper abdomen, but the supply is so wide that one would have the choice of division of the three splanchnic nerves and the sympathetic cord on either side, giving eight alternative paths, and one cannot help but feel that if the pain is due to sympathetic overaction relief should lie in the future, not in the cutting off of the afferent and efferent impulses along the sympathetics by surgical treatment, nor by controlling these impulses with medical treatment and drugs, but rather by the wider introduction of a healthier open-air life. These patients should, in fact, make use of the prescription given us some time ago by Kipling: "They should dig till they gently perspire."

MANCHESTER INSURANCE COMMITTEE: OPENING OF NEW OFFICES.—In connexion with the formal opening of the new offices of the Manchester Insurance Committee at Ardwick on June 28th, Mr. L. C. Brock, Principal Assistant Secretary to the Ministry of Health, said they had succeeded in securing the smooth working of a medical service which now embraced 13,000 doctors, a full third of the population, and covered the whole country. The medical service had been steadily improving, but there was one feature which gave ground for uneasiness—the steady and continuous increase in the expenditure on and in the consumption of drugs and medicines. This applied particularly to Manchester. During the last year the insured population of England and Wales got on with rather less than 4½ prescriptions per head; but in Manchester they were 6·60 and in Salford 6·84, so that Manchester received 50 per cent. more prescriptions than the average of the country as a whole. Each Manchester prescription cost a little more than 9*d*. This was indicative of a wrong attitude of mind on the part of the insured population. Moreover, the consumption of dutiable medicines had increased, and it looked as if we were on the way to becoming a nation of medicine drunkards.

The Manchester Insurance Committee is responsible for the adequate medical benefit of more than 330,000 insured persons. During the last year over £140,000 was disbursed by the committee for medical treatment, comprising about 2,000,000 services and upwards of £77,000 for medicines and appliances. In the 15 years of medical benefit up to last December the total expended in Manchester on treatment was nearly £1,700,000, and on medicine and appliances £582,000.

LACTIC ACID MILK AS A ROUTINE INFANT FOOD.

BY JAMES A. STEPHEN, M.B., D.P.H.,
MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE, ABERDEEN;
AND
EDWARD R. C. WALKER, M.B., CH.B. EDIN.

LACTIC acid milk has for several years been extensively used by pediatricians in America as an artificial food for infants. It has not, however, received much attention in this country. Its most prominent advocate is W. M. Marriott, of St. Louis, whose work one of us (E. R. Walker) had the opportunity of seeing three years ago. The results seemed so satisfactory, and compared so favourably with those obtained by other methods of feeding, that we determined to give it a thorough trial. This paper is based on a study of 50 infants so fed at the Burnside Infant Welfare Home, Aberdeen.

Marriott and Davidson [1] analysed the records of all infants under 1 year of age in the St. Louis Children's Hospital for a period of two years, during which whole lactic acid milk was used as a routine feeding. Infants suffering from proved tuberculous meningitis and septicæmia were excluded, but no other selection was made. From the remaining 142 records the following results were obtained. The average period of feeding was 22 days, and the average gain 0·9 oz. Commenting on this, the authors say: "This satisfactory nutritional result in a group of sick infants under hospital conditions has served to confirm our original impression of the value of the food of type described." They state that the infants rarely developed diarrhœa or vomiting, whilst the mortality amongst athreptic (marasmic) infants fell from 78 per cent. four years earlier to 26 per cent.

Rationale of "Buffer" Action of Milk.

The acid-binding or "buffer" value of sweet cow's milk is three times that of human milk, and it is this characteristic which chiefly renders cow's milk difficult of digestion by the infant. Marriott and Davidson [2] have shown that in infants fed on whole cow's milk the H-ion concentration of the gastric contents is greatly lowered. The deleterious effects of the lowered gastric acidity thus produced are of importance. The bactericidal properties of the gastric contents are distinctly reduced, and the alterations in digestive processes are numerous. Peptic digestion is seldom possible at the concentrations reached, which in Marriott's cases averaged pH 5·1, peptic digestion beginning at pH 4 and being optimum at pH 2·5. The importance of peptic digestion is not completely understood, but it is believed that the peptone so formed has a stimulating effect on the flow of bile and pancreatic secretion.[2] Of greater importance, however, is the denaturation of protein by rennin coagulation. The latter occurs at a pH about 5·5, and any lesser acidity than this favours the passage of unchanged protein through the pylorus. This is of particular moment in athreptic infants and in normal infants of less than two weeks old, in whom it has been shown that unchanged protein can pass through the intestinal wall into the general circulation.[3] It is conceivable that this process may be sometimes of ætiological importance in the rare cases of idiosyncrasy to cow's milk. Many infants, of course, by acquiring greater powers of gastric secretion overcome these difficulties and apparently thrive on whole milk. It is difficult not to feel uneasy about the possible after-effects of this over-secretion, and Pritchard [4] has recently recorded his misgivings on that score. Sweet whole milk, however, is not often advocated nowadays.

Dilution of Cow's Milk.

Dilution of cow's milk will get over these faults, but is unfortunately attended by defects of its own. Clinically it has been recognised as desirable to lessen the degree of dilution as soon as this may be successfully accomplished without digestive upset in the infant. The explanation of the shortcomings of high dilutions is to be sought in the nature of the proteins of the two milks. Of the two principal proteins—lactalbumin and caseinogen—lactalbumin much more closely resembles the body proteins in the composition than does caseinogen, and 54 per cent. of the protein of human milk is lactalbumin as against only 14 per cent. in cow's milk. Cow's milk is, therefore, for the purpose of feeding human infants, relatively deficient in essential amino-acids, notably tryptophane, and much more of its proteins must be fed if the full complement of "building-stones" is to be provided. Since the total protein of cow's milk is three times that of human, feeding whole milk will meet the requirements.

Lactic Acid Milk.

From these considerations it appears that some other method than dilution should be attempted in order to render cow's milk suitable to the infant digestion. To this end acid can be added to whole milk in amounts calculated to overcome the excess of "buffers" and so maintain in the infant's stomach an H-ion concentration similar to that occurring in natural feeding. Hydrochloric acid, vinegar (acetic acid), lemon juice, and lactic acid have all been used. Hess [5] has recently advocated orange juice for this purpose. It has apparently a favourable effect on protein solubility. Hydrochloric acid would seem to be the most logical one to choose, and has been strongly championed by some workers, notably Faber.[4] It has, however, certain disadvantages. It is an inorganic acid, and therefore tends to lower the body alkali reserve when given in amounts large enough to exert its anti-buffer action in the stomach. Also, according to Wills, Sanderson, and Paterson,[7] it seriously lessens the retention of calcium. Lactic acid is an organic acid occurring naturally in the metabolism of muscle and other cells, and is completely oxidised in the tissues. It has also the advantage that at the concentration necessary to produce its anti-buffer effects lactic-acid forming organisms alone can flourish, whilst pathogenic organisms are destroyed or at least inhibited (see table).

Table showing Effect of Lactic Acid on the Bacterial Count of Milk.

Sample No. 1.

	Count per c.cm.	*B. coli* present in—
(*a*) Lactic acid portion.		
1st pl. 2 hrs. after L.A.	800,000	0·01 c.cm.
2nd pl. 24 hrs. after L.A.	128,000	0·01 „
3rd pl. 48 hrs. after L.A.	170,000	0·01 „
(*b*) Control portion.		
1st pl.	2,000,000	0·01 „
2nd „	6,400,000	0·01 „
3rd „	7,400,000	0·01 „

Sample No. 2.

(*a*) Lactic acid portion.		
1st pl. 2 hrs. after L.A.	6,000	0·1 „
2nd pl. 24 hrs. after L.A.	1,300	0·1 „
3rd pl. 48 hrs. after L.A.	900	0·1 „
(*b*) Control portion.		
1st pl.	17,000	0·01 „
2nd „	19,000	0·01 „
3rd „	27,000	0·01 „

pl. = plating. L.A. = addition of lactic acid.

These counts were made by Dr. Smith, bacteriologist to the City Hospital, Aberdeen, to whom our thanks are due.

Naturally, soured milk—i.e., by inoculation with *B. acidophilus* or other lactic acid producer—is probably the best form for infant feeding, but a quite satisfactory form can be prepared by the addition of pharmacopœial lactic acid to whole milk, in the proportion of 1½ drachms to the quart. This gives a concentration of about 0·5 per cent. The acid is stirred into the milk (which must be cold), the last half being added very slowly drop by drop, and thoroughly stirred in, to prevent the formation of

large curds. As the last drops are added a fine flocculent curd appears. Sugar is added in the amount and in the form considered advisable. Most healthy infants will take cane-sugar quite well, and this can be conveniently added in the form of golden syrup in the proportion of one or two tablespoonfuls to the pint. In very young or weakly infants, where larger amounts of sugar may be required, a less fermentable sugar, such as dextri-maltose, is desirable, since considerable amounts can be taken without causing diarrhœa. Marriott [8] recommends corn syrup, which is prepared by the acid hydrolysis of starch, and contains approximately 55 per cent. dextrin, 30 per cent. maltose, and 15 per cent. glucose, and which has the additional advantage of being very much cheaper than dextri-maltose. Unfortunately, it is not easily procurable in this country; Mellin's food, however, is a comparatively cheap form of dextri-maltose.

Whole Lactic Milk Feeding.

In practice, milk prepared in this way possesses many advantages as an artificial food for infants. In preparation it is very nearly "fool-proof"—certainly more so than any satisfactory method of dilution feeding. Owing to its antibacterial properties it keeps well, and the whole 24 hours' supply can be prepared in about a quarter of an hour and put aside to be used as wanted. On account of its maintaining a physiological H-ion concentration of the gastric contents, it enables the infant to deal satisfactorily with food to the full amount of its nutritional requirements, even in the presence of parenteral infections, which are usually accompanied by serious lowering of the gastric acidity and handicapping dyspepsia. Healthy infants on whole lactic acid milk gain weight steadily and satisfactorily in the manner usually associated with healthy breast-fed infants, and like these they are firm and their muscles are of good tone.

Modifications of Whole Lactic Milk.

Certain modifications of the ordinary lactic milk are sometimes indicated. Various sugars can, as has been indicated, be used according to the nutritional and digestional requirements. Skimmed lactic milk is often very useful. It is prepared in the same way as the ordinary form, using skimmed instead of whole milk. It is of value in cases of fat intolerance with large soapy stools and failure to gain weight—Finkelstein's "Disturbance of Equilibrium." It is often helpful in diarrhœa cases, especially dysentery and enteral diarrhœas, where presumably the fatty acids, which are tolerated by a healthy mucosa, add insult to injury in one already irritated by bacteria and their toxins. Protein in some such form as Mead's "Casec" may usefully be added to raise the calorie value of the mixture and lessen fermentation.

Contra-indications.

With regard to contra-indications it seems, according to Wills, Sanderson, and Paterson,[7] that there is some reduction in the percentage retention of calcium, but since very considerable excess of this element is present, this does not seem to be of serious import. No signs of deficiency as a result of whole lactic milk feeding have been observed.

Of more serious significance is the observation of Clausen,[9] that in the presence of anhydræmia or circulatory failure from any cause there may be a very marked increase in the blood lactic acid, as much as 150 mg. per 100 c.cm., as compared with the normal 10–30 mg. with the production of acidosis. It would seem unwise in such a case to give lactic acid milk until the anhydræmia had been overcome, with resultant disappearance of the acidosis. Incidentally, it appears that over-enthusiastic attempts to combat the acidosis in these cases by means of alkalis has not infrequently led, when the acidosis had rapidly disappeared, to alkalosis, tetany, and death. A good many infants have probably been killed by baking soda. The aim in such cases of anhydræmic acidosis should be to restore the blood volume and circulatory function as early as possible by means of fluids administered enterally and parenterally, the acidosis disappearing spontaneously when this is accomplished.

There is considerable difference of opinion regarding the suitability of acid milk as a food for very young infants. Marriott considers that it can be used safely and with advantage from birth. Faber [6] recommends that it should not be used for infants under six weeks, while Parsons [10] gives three months as the earliest age for its exhibition. We have used it with gratifying results in several cases under three months. Faber gives the theoretical considerations which led him to set the limit at six weeks. Breast milk for the first ten days of lactation contains more or less colostrum and has a definitely alkaline reaction. The stomach of the new-born infant holds about 1 oz., so that if a feed, say, of 3 oz. be taken, a large part of it must pass through very soon into the small intestine, and much of the digestion must be intestinal rather than gastric. From this he concludes that it may well be advisable by increasing the alkalinity to lower the buffer resistance to alkaline change. Against this view it must be remembered, as has been pointed out, that such low H-ion concentrations favour the passage of unchanged protein through the pylorus, and that this, while it is probably of little moment and may even be of value in the case of human milk, is very possibly not without danger when cow's milk is being used. Indeed, Anderson and Schloss [3] have suggested tentatively that the entrance of the foreign protein of cow's milk into the blood of infants may have some causative relationship to the nutritional disorder in which it is found. Since whole lactic milk has a much higher calorie value than breast milk and dilution formulæ, a similar volume will meet the nutritional requirements. If not more than 2 oz. be given at each four-hourly feed and sterile water be given between feeds to maintain the optimum fluid intake, most of the early digestion is likely to be gastric, and duodenal disturbance will thus be largely obviated. One of the cases here reported was on lactic milk from birth, and has never been below the normal healthy weight line, in spite of a fairly sharp attack of bronchitis. Nevertheless, there can be no doubt that it is in the first month that it is most difficult to find a satisfactory substitute for natural feeding, and in our series the happiest results have been obtained in those infants who have had at least a month of breast feeding.

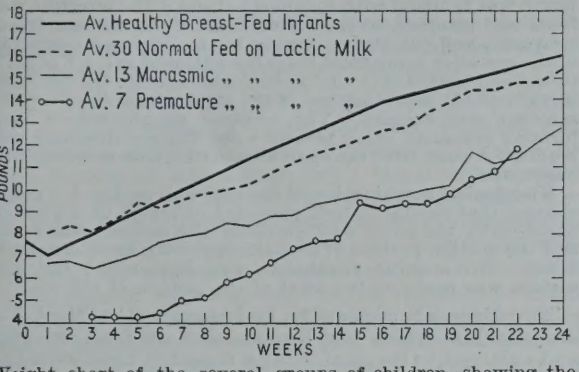
Results of Lactic Milk Feeding (50 Infants).

Every one of our 50 cases had at some time during the period of observation an upper respiratory infection, usually the ordinary "nasal discharge." Five had pneumonia, five dysentery (Sonne bacillus), and three whooping-cough, so that there was no undue selection. The age-period at which they were studied was 0–6 months, since after the latter age they almost all had additional food. The period of observation varied from two weeks to six months, the average being 8·8 weeks. The average weekly gain in weight was 5·0 oz. There were seven deaths during the period under consideration. The causes of death were as follows: Pneumonia, three; marasmus, two; prematurity, one; enteritis, one. The infants were divided into three groups: (1) normal, or slightly subnormal; (2) marasmic; and (3) premature. The accompanying weight chart of the three groups is self-explanatory.

Group 1.—There were no deaths in Group 1 in which there were 30 infants. The average gain in weight in these was 6·0 oz. per week. Three of these had whooping-cough, two dysentery, and one pneumonia. Amongst the remaining 24 the average weekly gain was 6·5 oz.

Group 2.—As a criterion for Group 2 we took Leonard Parsons's definition of marasmus: "The basal metabolism of the infant has been found to fall outside the limits of the normal when the child had lost one-fifth of its body weight. A child, therefore, can be considered as marasmi

if its weight is less than four-fifths of the expected weight for its age." There were 13 infants in this group. The average weekly gain was 3·9 oz. Two had Sonne dysentery and one pneumonia. Excluding these the average gain of the remaining ten was 4·5 oz. Three of this group died, one of pneumonia, while the cause of death in the other two cases was given as marasmus.



Weight chart of the several groups of children, showing the results of lactic milk feeding.

Group 3.—There were seven premature infants, of whom four died, two of pneumonia, one of enteritis, and one of prematurity. The average weekly gain was 2·7 oz. Another had Sonne dysentery and survived. She is now doing well. Of the two who escaped serious illness, one gained 26 oz. in three weeks and the other 29 oz. in nine weeks.

Summary.

1. Fifty infants have been fed with lactic acid milk as a routine food. They varied in age from 1 day to 6 months, and the results were very satisfactory, comparing most favourably with those obtained with ordinary methods of dilution feeding.

2. The advantages of milk of this type as an infant food are: (*a*) Preparation. The milk is easily prepared, requiring no complicated calculation. The whole 24 hours' supply can be prepared at one time. (*b*) Relative sterility: On account of its nature, the milk remains free from harmful organisms for a considerable time. (*c*) Digestibility: The overcoming of the high "buffer" value of the sweet milk renders it easy of digestion for the infant. (*d*) Calorie value: The milk has a high calorie content, so that the full nutritional requirement can be given without excessive bulk.

3. The milk can be suitably modified in pathological conditions.

4. The milk should not be used in cases of anhydræmic acidosis until the acidosis has been overcome. Some authorities hold that acid milk should not be fed during the early weeks of life. We have used it in several infants of a few weeks old, and neither theoretical considerations nor clinical experience has led us to subscribe to this caution, provided reasonable care is exercised and over-feeding guarded against.

Clinical and Laboratory Notes.

VERTEBRAL FIBROSIS:

"CELLULITE" OF THE NECK.

BY DR. HENRI FORESTIER,
AIX-LES-BAINS;
FELLOW OF THE ROYAL SOCIETY OF MEDICINE.

THE fibrosis of subcutaneous connective tissue called "panniculitis," and the fibrositis of muscles, their fasciæ and sheaths, have been the chief localisations described by Swedish physicians under the name of "cellulite," and mentioned by L. L. Jones Llewelyn [1] in 1915 and Ralph Stockman in 1920. We have, I believe, no account of any other localisation.

I have for three years observed [2] at Aix-les-Bains in rheumatic and gouty patients on the one hand *nodules* located in the suboccipital region, on the transverse processes of the atlas, and on the other hand in the cervical grooves deep-seated *thickenings*, probably juxta-periosteal, which I believe to be due to "cellulite." This "cervical cellulite" gives rise to headache or to neuralgic pains radiating down the shoulders, the arms, and even precordial region, phenomena which may escape one's investigation and cannot, therefore, be properly treated until the practitioner ascertains their cause.

The following statement made by Stockman [3] confirms my opinion:—

"It is remarkable that this condition has attracted so little attention from medical writers. By Swedish physicians and masseurs the name 'myit' has for long been given to muscular rheumatism, and 'cellulite' to the somewhat similar pathological condition affecting the subcutaneous tissue. But until comparatively recently the latter has been almost unrecognised outside Sweden."

If the "cellulite" of muscles and the "panniculitis" which are comparatively easy to recognise have escaped observation, as Stockman says, *a fortiori* have the deep-seated nodules and the thickenings due to the cervical fibrosis passed unnoticed.

Signs of Cervical "Cellulite."

For the detection of the cervical "cellulite," the patient must either sit astride of a plat-backed chair facing the doctor, his arms crossed over the back of the chair, his forehead leaning on his arms, or be simply seated, his head leaning against the chest of the doctor. In either position the muscles of the neck are relaxed to allow of deep palpation. On both sides the tips of the fingers begin first to explore symmetrically the mastoid region and the transverse processes of the atlas. Then, getting nearer the median line, they penetrate the cervical grooves and gradually descend to the shoulders.

The knotty condition of the atlas feels like a globular tumour the size of a little nut, capping its transverse process, and more or less painful on pressure. The tumour is usually unilateral and situated on the left side. Its outline is sometimes sharp, at other times not clearly defined, and it may involve the transverse process of the axis. The thickening in the cervical groove appears either as a round cord or as little swellings, varying in size from a split pea to an almond, extending over several vertebræ, parallel to the articular processes, hard, tender on pressure, giving rise to pain radiating down the arm. It is to be noted that these conditions are much more frequently met with on the left side.

Diagnosis.

In the suboccipital region the anatomical conditions are most favourable for the development of

[1] L. L. Jones Llewelyn and A. Basset Jones: Fibrositis. London.
[2] Cellulite Vertébrale du Cou, Société Médicale de Paris, Mars, 1924.
[3] Ralph Stockman: Rheumatism and Arthritis. Edinburgh, 1920, p. 62.

"cellulite"—a remarkable association of tendons, ligaments, aponeuroses buried in connective tissue. The transverse process of the atlas gives attachment to numerous ligaments, tendons of six muscles, and their serous bursæ.

Radiography shows that these nodules and thickenings are not of bony origin, although it may happen that juxta-periosteal "cellulite" turns into osteo-periostitis, and thus produces a true bony nodule or an exostosis. Such pathological development is pretty frequently met with in gouty or so-called "arthritic" patients.

It is easy enough to differentiate a gland from the nodules or cellular tissue thickenings of the cervical space, for the glands are movable. It is a question of experience and delicate palpation which needs practice and much patience.

Symptoms.

Two kinds of symptoms are caused by cervical "cellulite": aches and joint troubles. Aches are by far the dominating symptom. According to the seat of the "cellulite" they differ.

To the "nodule" of the transverse process of the atlas are due headaches, cervico-occipital or epicranial neuralgias. To the thickening of the cervical groove is due the cervico-brachial neuralgia or neuritis with sometimes *pseudo-cardialgic* symptoms. Patients complain of a dull aching pain in the nuchal region and of permanent or intermittent pains spreading to the arms, occasionally accompanied with paræsthesias, numbness, and tingling sensations in the hands.

The pseudo-cardialgic symptoms are highly interesting on account of the errors of diagnosis they may lead to. They correspond to the irritation of the roots of the fifth and sixth cervical pairs. The pain is, as in sciatica, increased by effort and cough, and may make the patient anxious about his heart. Within two years Prof. Vaquez and I have met with two such cases.

Articular troubles.—The joint troubles caused by the "cellulite" consists in a certain stiffness of the neck and of the head. The amplitude of the movements is limited by a certain degree of contracture of the muscles, resulting from the painful joints of the articular processes (rotation of the head, lateral and antero-posterior flexion). In consequence the patient has to find for himself a good position in bed to rest his head, and is often awakened in the night by recurring pain due to the shifting of his position during sleep. Vertebral "cellulite" of the neck has been observed by me in arthritic subjects very frequently; about 20 per cent. of the cases of gout and chronic rheumatism.

The *treatment* by Aix methods: local natural vapour baths (radio-active) applied to the neck, followed by general and local douche-massage, has been most satisfactory. At home patients may be benefited by hot-air applications and skilled massage.

AN UNUSUAL CASE OF INGUINAL HERNIA.

BY W. B. JOHNSON, M.B. LOND., F.R.C.S. ENG.,
SPECIALIST, WEST AFRICAN MEDICAL STAFF.

THE following case presents features of interest which seem to be worthy of record.

A male native, aged about 45, was sent to me from a pagan district in the Northern Provinces of Nigeria with a large scrotal swelling reaching to the level of the knees. The history was indefinite, as nobody understood the patient's language, but it appeared that the swelling had been present for many years and that it had given pain and discomfort for several weeks. He was running an evening temperature of from 99° to 101° F. The bowels were opened with aperients.

Operation was performed under spinal anæsthesia with the assistance of Dr. W. E. S. Digby. The condition proved to be a right inguinal hernia with acquired sac. At the neck of the sac, below the external ring, lay a loop of small intestine which was adherent to the sac wall. Attached to the loop by a broad pedicle, and completely filling the greater part of the sac, was a cyst containing 4¼ pints of brown semi-purulent fluid (presumably infected blood-clot). The cyst wall varied from ⅛ to ¼ in. in thickness, and the cyst was entirely shut off from the gut. Below the hernial sac, at the bottom of the scrotal swelling and entirely separate from the sac, lay the testis, the tunica vaginalis containing a small hydrocele of clear, straw-coloured fluid.

The cyst was cut away from the intestine, the wall of which was repaired with Lembert sutures; the intestine was freed and returned to the abdomen, and the sac was freed, ligatured, and cut away. Owing to the damaged condition of the gut after being freed from the adherent sac, a Kocher's tube was inserted into the peritoneum through the sac, and in view of the septic nature of the fluid within the cyst the scrotum was drained. The scrotum suppurated—a gas-forming organism being present—and further drainage was required a week after the operation. Otherwise recovery was uneventful.

Histological examination of the cyst wall by Dr. A. Connal showed that the inner wall consisted of layers of organised blood-clot; the outer wall consisted of a serous membrane, and the median portion of fibrous tissue with areas of muscle fibres. No mucous membrane was discernible, but the section was made at the level of the pedicle of the cyst.

The diagnosis appears to lie between (1) a Meckel's diverticulum which had become shut off from the gut and enlarged to its great size by repeated hæmorrhages into its interior, or (2) a degenerated fibromyoma of the gut wall.

A CASE OF PNEUMOCOCCAL SEPTICÆMIA.

BY A. L. B. STEVENS, B.M. OXF., M.R.C.S. ENG.

THE following case seems to be of interest:—

The patient was a schoolboy, aged 15½. He had had a chronic discharge from his right ear for some years and was also subject to asthma. At the beginning of February, 1927, he ran a slight fever of 99° F. and was confined to bed for a few days, afterwards making a satisfactory recovery. Many of his schoolfellows were ill in bed with similar symptoms at the same time.

On Feb. 15th he complained of earache and was put to bed. On the 16th his right ear began to discharge freely, signs of bronchitis developed in the chest, and in the evening temperature rose to 104·6° F. On the 17th there was a sharp attack of epistaxis and the temperature again rose to 105° F. in the evening, the ear still discharging freely. Signs of bronchitis became more marked and some blood-stained sputum was coughed up. Epistaxis recurred on the 18th, 19th, and 20th.

On Feb. 18th there was a sharp attack of hæmaturia which also persisted until death. On the morning of the 19th there were early signs of consolidation at the right base and by evening the whole of the right lower lobe showed typical pneumonic consolidation. The patient was restless and bright-eyed; there was a hectic flush on each cheek and he was suffering from want of sleep. Sharp pleuritic pain developed in the right side the same evening. The abdomen was tumid and there was definite enlargement of the spleen which was tender on pressure.

A blood culture was done the following day, Feb. 20th, and in 17 hours pure cultured pneumococci were obtained from all five tubes. The white cells of the blood taken at this time numbered 22,900. In the afternoon of Feb. 21st the patient became collapsed and perspired profusely. He died at 6 o'clock the same evening.

Throughout the illness there was no evidence of petechial hæmorrhages on the skin. There was at no time any indication of headache or other signs indicating involvement of the central nervous system. The case appears to be worth recording because of the acuteness of the infection and because it is comparatively rare to find that septicæmia of such virulence is due to pneumococcus. References in medical literature are few.

WESTMINSTER EYE HOSPITAL.—The foundation-stone of the new premises of the Westminster Eye Hospital in Broad-street, Bloomsbury, was laid last week by the Duke of Connaught, who spoke of the innovation of setting apart 14 rooms in the new hospital for patients who could not afford a nursing home, but were willing to pay for comparative privacy. It is estimated that the new hospital will cost between £20,000 and £25,000 a year as compared with the £10,000 needed for the old premises at Charing Cross.

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A MEETING of this Society was held in the new Institute of Preventive Medicine at Cardiff on July 1st and 2nd, Prof. E. H. KETTLE in the chair.

A. LEITCH (London) had found that the pancreas of a hen bearing a Rous sarcoma without any metastases would originate a tumour if minced up and inoculated into a fresh hen; the liver and other organs, similarly treated, gave negative results.—S. RUSS (London) immunised rats with injections of tumour tissue treated with X rays; those which were resistant to subsequent implantations of the same living tumour were also more or less resistant to other tumours; the reciprocal efficiency of immunisation varied among two sarcomata and two carcinomata.—F. A. PICKWORTH (Birmingham) found that a remarkably high proportion of asylum patients agglutinated typhoid, Gaertner and other allied bacilli; the homologous and heterologous responses to typhoid vaccine varied a great deal in different individuals. He suggested that chronic subinfections played some part in their mental state.—P. BRUCE WHITE (London) distinguished three kinds of unspecific agglutination, working mostly with rough Salmonella variants; simple salt sensitiveness, removed by extraction with alcohol and restored by encrusting the extracted lipoids on to the bacilli again; with heated rough strains alcohol had no effect; agglutination with any serum is removed by extraction by alcohol, leaving the specific serum agglutinability unaltered.—J. A. ARKWRIGHT (London) showed that agglutination by somatic and by flagellar agglutinins could be clearly distinguished microscopically, the clumps in the former moving about as a whole by the action of the free flagella.—G. H. EAGLES (Beckenham) had tried a Ramon flocculating test with scarlet fever toxin and antitoxin and found that the results had no relation to the neutralising power as measured by the skin test.—H. R. DEAN (Cambridge) had with some difficulty demonstrated that complement fixation does occur in toxin-antitoxin mixtures at about the same relative concentrations which give the best precipitation.—P. HARTLEY (London) tested the antigenic value of Ramon precipitates from diphtheria toxin; it is considerably depressed by the simultaneous injection of muscle extracts but not by peptone solutions.—T. DALLING (Beckenham), repeating his work of the previous year on the prevention of lamb dysentery, showed that less than 1 per cent. of the lambs of ewes dosed with welchii toxin-antitoxin died of the disease, while more than 8 per cent. of the lambs of control ewes succumbed. Of lambs receiving a dose of welchii antitoxin soon after birth 1 per cent. died compared with 20 per cent. of the controls. The variety of *B. welchii* which was constantly isolated from infected animals in Roxburgh, Northumberland, Wales, and Wilts seemed peculiar in several respects and may possibly prove to be another species.—J. F. GASKELL (Cambridge) had noticed that the virulence of pneumococci in culture is consistently lower in the summer months than it is during the pneumonia season from December to April, and that severe experimental lesions can best be obtained during the winter months.—H. D. WRIGHT (London) showed that the difficulty of testing the bile solubility of pneumococci in cultures containing serum and glucose arose from an acid precipitation of proteid.—J. MCINTOSH and P. LAZARUS-BARLOW (London) for testing the fermentation reactions of streptococci recommended the use of poorly buffered media, phenol red as indicator, and rigorously purified sugars.—S. P. BEDSON (London) showed that the virus of herpes hardly ever comes through collodion filters which pass a good deal of the accompanying proteid; the virus must therefore be larger than the proteid molecule.—G. W. T. H. FLEMING (Dorchester) demonstrated the value of Jahnel's method for staining spirochætes in the nervous system.—A. PINEY (London) had studied the effect of large doses of X rays on the blood of rabbits. A pronounced leucopenia is followed by a transitory leucocytosis, lymphocytes are permanently diminished, red cells not much altered though nucleated forms may be abundant. The most marked internal changes are in the spleen and the animals waste away and die in about a month.—L. J. WITTS (Cambridge) described how the large lymphocytes, monocytes, and clasmatocytes of the blood and exudates could be readily distinguished by Sabin's supravital technique with neutral red and Janus green.—C. H. WHITTLE (Cambridge) found that agar or egg cultures were satisfactory for the routine determination of the mouse virulence of pneumococci.—R. W. BROOKFIELD (Liverpool) discussed the relationship between red cells showing punctate basophilia and reticulocytes in patients under treatment with lead colloid. On the whole the two vary in abundance in parallel and it is suggested that the stippled cells are regenerative forms (reticulocytes) modified by the toxic action of lead.—R. W. SCARFF (London) by feeding rabbits for a long time with cholesterol produced a considerable increase in blood cholesterol, no change in blood pressure, and extensive atheroma of the aorta and its larger branches without change in the smaller vessels. Changes most similar to those of human atheroma were obtained by feeding with cholesterol for six months, and then leaving the animal for six months before examination.—E. E. GLYNN and A. D. FORDYCE (Liverpool) exhibited a well-marked example of precocious sexual development in a boy of 2 years of the "infant hercules" type. There was a tumour of the left adrenal with metastases in lung and brain. The right adrenal was atrophied; pituitary and thyroid normal.—H. H. GLEAVE and G. WILSON (Sheffield) dealt with a case of suprarenal virilism in a women of 36, cured by removal of the tumour.—C. J. POLSON (Manchester) described a number of rabbit tumours (myosarcoma and carcinoma of uterus, carcinoma of kidney, endothelioma of peritoneum, &c.), two examples of lithopædion in rabbits, and an unrecognised carcinoma of breast which was the origin of extensive metastases.—G. S. WILLIAMSON and INNES H. PEARSE (London) pointed out that the active secretory (adenoid) tissue of the thyroid, commonly abundant in the fœtus, about puberty and during pregnancy, contains no iodine and none of the differentiating substance revealed by the tadpole test.—G. S. WILLIAMSON and HILDA CUNNINGTON (London) demonstrated the relation of the iodine content and tadpole activity of a number of different human goitres.—C. M. ACLAND (Cardiff) exhibited her method of mounting museum specimens in celluloid boxes.—S. L. CUMMINS (Cardiff) showed specimens illustrating the effect of sanocrysin on rabbits infected with tuberculosis, J. GORDON and F. C. HAPPOLD (Leeds) a carcinoma of the ovary in a hen, H. COLLINSON and M. J. STEWART (Leeds) a chronic ulcer of the stomach with miliary tuberculosis of the mucosa, C. E. JENKINS (Manchester) a new form of porcelain filter allowing the use of small quantities of liquid, E. E. GLYNN and C. H. WALSH (Liverpool) achalasia of œsophagus, the lungs in asphyxia from hæmoptysis and preparations from a case of? quinidine poisoning, E. H. KETTLE and J. MILLS (Cardiff) specimens illustrating defence rupture in experimental streptococcal infections by calcium salts and other chemicals, and B. T. TERRY (Nashville) a rapid method of histological diagnosis by staining only one side of thick freehand sections.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

THIRTEENTH ANNUAL CONFERENCE.

THIS conference was held at the House of the British Medical Association on June 30th, July 1st, and 2nd. There was a large attendance of medical men and women, and representatives of various local authorities from all parts of Great Britain and Ireland. Sir ARTHUR STANLEY (chairman of the Council) presided throughout.

OPENING BY THE MINISTER OF HEALTH.

The conference was opened by Mr. NEVILLE CHAMBERLAIN (Minister of Health). He said he was glad to pay official testimony to the work of the Association, which had a long and brilliant record of voluntary work. He had noticed in the annual report that 35,000 deaths from tuberculosis had taken place last year. If in the remarks he was about to make he emphasised rather the decline in the mortality, it was from no desire to be complacent about the position, but only because the degree of success attained in the past made it appear more worth while to persevere in their efforts. Fifty years ago the death-rate from all forms of tuberculosis was 287 per 100,000; last year the rate had fallen to 96—a reduction to almost exactly one-third. What was the cause of this great reduction? It had been shown by Sir Archdall Reid and others that by a slow process partial immunity was acquired by nations. Possibly this same process was still going on, but no proof was available, and he himself preferred to ascribe the drop in tuberculosis mortality to two other factors: (*a*) the improvement that had taken place in the social surroundings of the people, and (*b*) the adoption of special measures. Among the conditions which affected the health of the people one of the most dominating was housing. The strongholds of tuberculosis were to be found in close and dingy dens which still existed in their large cities. The efforts which had been made to purify and ventilate these foul spots must have had much to do with the improvement that had taken place in the tuberculosis statistics. Since the armistice 894,000 new houses had been built, and this alone could hardly fail to have its effect in the future. He hoped it might be possible for him to introduce further legislation facilitating the efforts of local authorities to improve conditions in the worst areas. He was aware that country districts as well as towns were not free from those evils. He would be disappointed if the Rural Workers Housing Act, which was passed last year and which made provision for the reconditioning, repair, and enlargement of cottages in the country districts, did not provide in the future vastly improved accommodation for agricultural workers. With regard to the second factor he had mentioned, the outline or framework of organisation created throughout the country was fairly complete. Theoretically provision was made for the detection of every case of tuberculosis. Some of those present, however, might remember the schoolboy's essay: "The horse is a noble animal, but he does not always do so." The general practitioner was a fine fellow, but he did not always do so, as far as notification was concerned. Tuberculosis was said to be not an easy disease to diagnose, especially in the early stages. But the tuberculosis officers had ample opportunities for examining cases, and their expert advice was always available. After notification came prevention; the health visitor visited the home, advised the patient, and, if necessary, reported the condition of the house to the medical officer of health. Here, too, there was sometimes room for the better working of the machinery. The *county* authority might have investigated the case and felt that housing conditions might be responsible for the disease, but it was the *district* authority which was responsible for seeing that the condition was improved, and these two authorities did not always see eye to eye. After diagnosis came treatment, either by the patient's own doctor or by the dispensary, sanatorium, or hospital, according to the case. But in addition to those processes which he had been describing there were two other aspects of the question which were not wholly official—education and after-care. He was not sure, indeed, that they were any less important than the others of which he had been speaking. Salvation could not be forced upon an unwilling people. A good deal of ignorance upon the subject of tuberculosis still prevailed; many did not understand its infectivity, others did not understand its curability. Education was part of the work which the Association was carrying on with such success. The success of treatment largely depended on the after-care of patients discharged with disease arrested but not cured. They must remember that such people were not normal and that many would never become so. A return to conditions which were insanitary or unhealthy would probably entail a further breakdown in health. Papworth and Preston Hall had given them a vision of hope, of a possibility of a better method, but it was clear that colonies of that kind must require careful organisation, and even then could deal with only a limited number of cases. Further experiment was very desirable in that and in other directions. The establishment of care committees, he thought, was the greatest service that could be rendered. He had the highest admiration for the voluntary task which the Association had set itself. To his mind theirs was a scheme not only of broadest humanity, but also one that had a real national economic value.

Sir JOHN ROBERTSON (medical officer of health, Birmingham; professor of public health, University of Birmingham) then introduced a discussion on

PRESENT LINES OF ATTACK ON TUBERCULOSIS: THEIR RELATIVE VALUE.

The lay public, he said, was becoming every year more anxious to get rid of tuberculosis, and they were prepared to do what was right and to pay what was necessary. They were, however, mystified by the multitude of counsels which were given, with the result that it was difficult to get the concerted and long-continued effort on the things that were of importance. Those who were brought into contact with the whole problem could realise that the reduction in the number of new cases was far more important than the discovery of any panacea for the cure of the disease. There was a great temptation to look after the sick in the case of an illness like this and to neglect the more important principles of prevention. He submitted statistics of incidence of the disease both for England and Wales and for the United States which showed that the influences which were at work in producing a high mortality among males in both countries were very similar. There was a high incidence amongst males between the ages of 20 and 45, the rate of mortality during these years being somewhat uniform, while among females the highest mortality-rate was reached in the age-period of 20 to 25 years, after which time it rapidly declined until the age of 50 years was reached. Another chart displayed showed that for each of the age-groups there had been during the past 25 years a large reduction in mortality, except in the age-groups for females between 15 and 25 years of age, in which there had been a slight increase. The reduction, he was convinced, was a real one. He had been particularly struck by the greatly reduced incidence of tuberculous adenitis, although no statistics as to this were available.

The three outstanding events which had probably exerted the greatest influence in reducing the incidence of, and mortality from, tuberculosis were: the introduction of compulsory general education in 1870; the discovery of the tubercle bacillus and the subsequent methods of immunisation; and the establishment of antituberculosis schemes with their tuberculosis officers, sanatoriums, hospitals, and dispensaries. Of all these factors he believed that the better education of the people had had the most far-reaching effect. There could be no doubt that a modicum of general education

made the people dissatisfied with their unhygienic conditions of life and with the amount and cost of the food-supply, nor could anyone doubt that the exercise of good general intelligence was perhaps the greatest asset in the campaign against tuberculosis. In a large poor-class district in Birmingham, where ignorance prevailed, the rate of mortality from the disease was four times what it was in another area inhabited by intelligent artisans. The most effective method in the campaign was the increase of knowledge of healthy living. He urged the paramount importance of suitable and adequate nutrition and of an abundance of fresh air and sunlight. A very great deal remained to be done in regard to the question of the feeding of the people, although a great improvement had taken place in the last 70 or 80 years in the amount and quality of food available for the labouring classes. There were still people in every class of society risking their health in the dull light and stagnant air of badly constructed workplaces or dwellings. All who had taken an interest in sanatorium treatment for tuberculous patients or for other debilitated people could have no doubt as to the effect on the general metabolism of the body of abundance of fresh air and sunlight, even in cases where a very ordinary diet was given.

Dealing with the question of immunity, Sir John Robertson said it appeared to him that specific immunity was not a thing of value when dealing with the whole subject of tuberculosis, for they must presume that those who had now contracted tuberculosis had at one time or another received some tubercle bacilli which ought to have protected them against subsequent disease. Theoretically this explanation of a general specific immunity conferred by small doses of living tubercle bacilli might be correct, but it appeared to him a dangerous proceeding, and he doubted if any practising physician would knowingly allow his own children to receive such doses. The whole question of the resistance of the individual to infection was a puzzling one, and all of those present must at times have had difficulty in understanding why tuberculosis did not spread in particular cases—e.g., of husband and wife. In other instances they had evidence that the tubercle infection was of a most diffusible type, as was well seen when an infected cow was brought into a cow-house containing animals free from the disease. In such a case his experience was that tuberculous infection in the cow-house was about as diffusible as the infection of measles. Summing up, the speaker said that what was needed above all was a better general education by which alone a community was capable of grasping the meaning and value of knowledge directed to such a special subject as healthy living. The better the education of the masses the better they were able to appreciate the reasons for adopting those measures which maintain health. Special education in the prevention of tuberculosis was also essential. The antituberculosis dispensary as a means of spreading knowledge was probably the most important weapon they had in their campaign against tuberculosis. The lessons taught there were not confined to the tuberculous or the suspects, but reached a large proportion of the population.

Discussion.

In the course of the short discussion which followed Dr. F. E. FREMANTLE, M.P., commenting on the fact that among males between 25 and 55 years of age tuberculosis mortality was almost at a standstill, whereas among females in those age-groups it was steadily coming down, suggested that it was because women were mainly at home and men were usually at work in shops or factories. He inferred from this that the source of infection was greater in factories and workshops than in the homes, however insanitary these might be. He thought that a great deal of the improvement that had been obtained in tuberculosis mortality was due to the earlier discovery of cases, and therefore to the lessening of sources of infection. The point he wished to make was the value of periodical medical examination of all insured persons, as was set out in the resolution submitted a day or two ago to the Minister of Health from the People's League of Health. He urged that medical men should address themselves to the task of discovering, defining, and arresting the cases of tuberculosis in this country.

Dr. E. E. PREST (medical superintendent of the Ayrshire Sanatorium) drew attention to what he called the persecution applied to persons who had been in sanatoriums. The difficulty of getting a person into a sanatorium was largely due to the fact that it was difficult for him to obtain work afterwards. For the same reason doctors were often unwilling to notify cases. In the Inland Revenue Service, if a man had been in a sanatorium he was damned. How, therefore, could a private person be blamed if he followed suit? He had had a case in which a man after years of ill-health had lost his pension; his own doctor had not certified him as suffering from tuberculosis, but another doctor to whom he went at last did certify him. That was why they very often could not get cases until they could be diagnosed by a policeman on his beat. At present, he said, it was necessary for a person to be notified before he could be admitted to a sanatorium; this ought not to be so. If a man handling meat were examined and found to be tuberculous he was immediately notified and removed from his occupation. The result of this kind of procedure would simply be that they would stop all butchers from being treated.

Another speaker referred to the dangers of migratory cases of tuberculosis. Patients came to health resorts from London or from various sanatoriums; they did not call in a doctor; they came in the busy season and the rooms were not disinfected after them—often even the bedding was not changed. He suggested that it should be obligatory on sick people to report themselves.

Dr. H. D. BISHOP (M.O.H., Guernsey) said that in a discussion on lines of attack they could not afford to omit a reference to the line of attack on bovine tuberculosis. Some 20 years ago Guernsey was considered to be free from tuberculosis. There was no case of tuberculosis among dairy cows. Later a few cows were sent to a dairy show in England and contracted tuberculosis. After they returned to Guernsey the tuberculosis mortality in human beings went up rapidly. For the last three or four years, thanks to unremitting care, tuberculosis in cattle had been unknown, and the tuberculosis mortality-rate had come down from 8·5 to 1·7. Incidentally the infant mortality had also come down; between 1910 and 1919 there were 41 deaths under 5 years of age, while during the past years there had been two only. An important regulation was that no animal was allowed to change hands, even between next-door neighbours, or to be exported without being tuberculin-tested. If a positive reaction was obtained that animal was followed up from farm to farm till they could be sure that the infection from that animal was stamped out. No less than 3000 animals were tuberculin-tested every year; last year there had been only two doubtful reactions, both of which on re-testing proved negative. The health of the bovine population was the health of the children.

The last speaker, Mrs. POWELL (L.C.C.), urged that attention should be concentrated on the health education of the young mothers and also of the children.

Sir JOHN ROBERTSON, in winding up the discussion, said that he would like to have heard suggestions from the meeting as to what could be done to make the country so healthy that tuberculosis could not get a footing. He believed that persons who were perfectly healthy would not contract tuberculosis. He agreed with the last speaker that education of the women and children in health matters was of the most fundamental importance. Education should even come before improvement in economic conditions, since such improvement would probably in any case follow in its wake.

At the afternoon session the subject of Housing: Home Conditions was discussed.

(To be concluded.)

Reviews and Notices of Books.

MENTAL DISEASES.

Mind and its Disorders. Fifth edition. By W. H. B. STODDART, M.D., F.R.C.P., Physician for Mental Diseases to St. Thomas's Hospital. London: H. K. Lewis and Co., Ltd. 1926. Pp. 593. 21*s.*

Dr. Stoddart's book ranks high among standard English works on psychiatry. It is written in a clear, concise style, and is equally valuable to the student and the practitioner. The general scheme of the work is excellent, commencing, as it does, with a simple yet comprehensive survey of academic psychology. These opening chapters are of importance since the fundamental functions of mind are too often neglected by the medical psychologist. Dr. Stoddart differs from McDougal in several points, notably he stresses the importance of affection as opposed to conation as the fundamental process of the mind.

For this edition some chapters have been extensively revised and others completely rewritten to bring them into line with recent advances in pathological research. The classification of instincts is taken directly from the Freudian school, with which the writer is obviously much in sympathy. The omission of any reference to the recent work of Pavlov and the Utrecht school on the conditioned reflex and the infracortical localisations is disappointing. The last chapter in this section is mainly devoted to the Freudian theory of the ego and its relationship with the instinctive trends; this relationship is but poorly presented. The second part of the book is devoted to the psychology of the insane; the opening paragraph is not very happy, since it seems to indicate that the psychology of the abnormal differs fundamentally from that of the normal, but the text does not carry out this idea. The third part deals with the actual clinical entities. The classification is clear and concise, the neuroses, psychoneuroses, and psychoses being specially well differentiated. The author regards Graves's disease as a psychoneurosis and amenable to treatment as such; in the light of our present knowledge of this condition this statement seems too dogmatic. The section on melancholia and its differential diagnosis is worthy of careful study; rest, both mental and physical, is insisted upon as the essential part of the treatment. Dr. Stoddart does not distinguish between the melancholia of the involutional state and the depressed phase of manic-depressive insanity, but appears to regard them as the same clinical entity. The ætiology of manic-depressive insanity is viewed from the psycho-analytic angle, and here the author fails to carry conviction. Epilepsy is ranged among the psychoses together with alcoholism and drug habits; this may appear revolutionary, but Dr. Stoddart's arguments in favour of his classification are impressive. His careful observation and clinical acumen are particularly well shown in the description of the physical stigmata and psychological make-up of epileptic patients; but he has followed the teaching of Pierce Clarke rather closely and is probably too optimistic as to the value of psycho-analysis. The chapter on general paralysis has been practically rewritten; the references to the older forms of treatment have been much abbreviated, and space devoted to tryparsamide and malaria. The clinical types suitable for malarial treatment might have been more fully discussed. Idiocy and imbecility are accorded their place in the general scheme, and there is a good chapter on Binet-Simon tests.

The clinical part of the book closes with a chapter on case-taking methods which should be of great importance to the student of psychiatry. There are useful practical hints on general treatment. The book ends with a chapter on the insane and the law, which has been carefully revised; the practitioner will find this of value. The appendix on pathology is well illustrated, but the subject matter is very brief. Dr. Stoddart's book has one grave fault—the frequent interpolation of the findings of the psycho-analytic school, which are neither accounted for nor explained. These spoil an otherwise well-balanced volume. The chapter on psycho-analysis is too sketchy to be of any real value. On the other hand, the student will appreciate the constant manifestation of the author's deep knowledge of organic neurology. Reference is made to the latest work in this field and its importance is never overlooked.

Mental Abnormality and Deficiency. An Introduction to the Study of the Problems of Mental Health. By Prof. SIDNEY L. PRESSEY, Ph.D., and LUELLA COLE PRESSEY, Ph.D., Ohio State University. London: George Allen and Unwin, Ltd. 1926. Pp. 356. 10*s.* 6*d.*

THIS book is intended as an addition to the library of social workers and others whose duties bring them into contact with the emotionally maladjusted and morbid members of the population. The range of the book is comprehensive, the writers stating that they have in view what might be called a course in "applied abnormal psychology." Several chapters are devoted to the art of "case taking"; the need for tact and discrimination are emphasised, and most valuable instruction is given on the range of facts to be acquired for each individual case. In this connexion it is noteworthy that the religion of the patient is never included as a fact to be noted; yet it is surely possible that this might give some colour to the psychic background, especially as it is occasionally stated that Roman Catholics are less prone to psychoneurotic disorders than members of other religious communities. The case studies quoted at length are illustrative of the methods employed and also of the various types of mental disorder.

The second part of the book is devoted to a classification of various mental conditions: normality, the borderline conditions, the functional and the organic mental diseases, and finally feeblemindedness. Special attention is devoted to borderline conditions, which are classified under three headings—the emotionally maladjusted, the emotionally unstable, and the mentally peculiar; the two former groups are correlated with the psychoneuroses, and the latter group with the psychotic personalities. The grouping is rather loosely carried out, the diagnoses not being always in conformity with generally accepted standards. Encephalitis lethargica is not even mentioned as a cause of mental disorder, although one of the cases quoted seems reminiscent of this disease. There are some rather wide generalisations; for example, the use of instruments at birth is suggested as a frequent cause of feeblemindedness. On the whole, however, the chapter on feeblemindedness is comprehensive and clear, the problem being regarded as a social rather than a eugenic one. The numbers quoted for the United States (6·5 per 1000 of feebleminded in men of the ages covered by a draft during the war) are interesting when compared with those of the Royal Commission which estimates 4·6 per 1000 of the total population of England and Wales as feebleminded. Causation and treatment are fully and helpfully discussed, although the rigid analyst may not appreciate the description of his technique as "that quiet but persistent inquiry with regard to the patient's emotional difficulty which is essentially 'psycho-analysis.'"

The writers emphasise the necessity for the early study of mental cases and state that as a matter of fact a diagnosis should be simply a first generalisation in the study of the case; the effort should always be directed towards an intimate personal understanding of the individual.

A wide bibliography is appended at the end of many chapters, and in the appendix the work of Tredgold and of Burt is given prominence. There is also a useful glossary. The style is lucid but careless in

places, and the phraseology may be unfamiliar to the English reader. But he will be missing an interesting and inspiring study if he allows these trifles to prevent him from a careful perusal of the book.

PUBLIC HEALTH PROPAGANDA.

Better than Cure. A Handbook of Public Health Propaganda. By D. M. CONNAN, M.B., B.S. Lond., D.P.H., and H. W. BUSH, A.R.San.I. London: Noel Douglas. 1927. Pp. 172. 6s.

THIS attractively written book is designed to teach the propagandist how to impart knowledge on the prevention of ill-health to the lay public. It deals in 14 concisely written chapters with the need for propaganda, what, whom, and how to teach, the use of apparatus for the purpose, and the results of public instruction. The authors have had three years of intensive experience of publicity methods in the Health Department of Bermondsey, and they have proved that it is possible to arouse a lively interest in health among the people of all ages and social grades. Their use of the kinema and the "multiposter" sign is most ingenious, and some of their couplets show a keen perception of the sort of thing the ordinary mind will easily grasp and retain. For instance, the element of surprise is well exploited in doggerel such as this:—

Shut your window, seal it down,
The surest way to a heavenly crown.

And even the pun is forgivable in the caption to a poster:—

Your Son and Heir
Needs Sun and Air.

Unfortunately all such teaching is apt to be unjustifiably dogmatic. At the very outset the reader may pause at such statements as "the cause of tuberculosis and the methods of prevention are quite well known." We doubt whether the causes of tuberculosis are well understood, and even whether the methods of prevention commonly advocated and practised are the main reason for the recent decline in this disease. Again, is it really "safe to say that at least half the sickness due to these two classes of disease"—viz., digestive and rheumatic—"would never have occurred had the sufferers learnt to take care of their teeth"? The writers deprecate the corporate attitude of the profession in relation to press publicity, believing that "this antiquated attitude of mind is in direct opposition to the trend of the times" and that "the press is deeply concerned in public health matters." We suggest that the attitude of the press to unqualified practice must raise doubts as to the character of their interest in such matters. It is true that the daily press is the most effective channel through which the public can be approached, but it is at least doubtful if the sort of copy acceptable in that quarter is of the highest educative value. We agree entirely with the statement that "quite an elementary knowledge of the principles of hygiene is all that is required, but that knowledge must be accurate." The fault we have to find with the propagandists is that, in a pardonable anxiety to give the people something easily understood, they are apt to forget where knowledge ends and theorising begins. In fairness we ought to say that the writers of the book themselves emphasise this point, but they might with advantage apply the criticism to some of their own teaching.

RADIOGRAPHIC DIAGNOSIS OF BILHARZIASIS.

By Dr. G. O. LOTSY, Member of the Cairo Institut d'Egypte. Cairo: H. Friedrich and Co. 1927. With 11 pages of plates. Pp. 29.

THERE is ample justification for the publication of this monograph. As stated in the preface, there are many elaborate works on bilharziasis, but none has dealt fully with the radiographic aspect. Nowhere could this work have been undertaken to better advantage than in Egypt, where the author is a well-recognised authority on this subject. The text, which is simple and direct, appears in three languages—French, English, and Arabic; considerable stress is laid on the differential diagnosis, for the radiographic appearances of urinary bilharziasis are apt to be a source of difficulty to the young radiologist. In this condition the ureters are frequently involved, and it may be associated with ureteric calculi. These are well seen in the excellent plates, where the outline of the heavily infected bladder sometimes appears quite plainly. In intestinal bilharziasis the deposits of eggs in the large intestine give well-defined opacities of peculiar appearance. The admirable diagrams which accompany the plates greatly enhance their practical value.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of London.

The estimated population for 1926 was 13,230. The day population of persons actively engaged in the City is about 440,000 and possibly 1¼ millions of people and 100,000 vehicles enter and leave the city daily.

The 106 births and the 138 deaths allocated to the small resident population made rates of 7·1 and 10·4 respectively. Some of the classified death-rates were: tubercle, 0·91; cancer, 1·28; respiratory diseases, 2·0; and organic heart disease, 1·4.

The infant mortality-rate was 66, that for the whole of London being 64. There were no deaths from influenza and no notifications of puerperal fever or deaths of mothers from childbirth.

Dr. W. J. Howarth, the medical officer of health, states that although considerable improvement has been effected under the new Meat Regulations, it will be some time before conditions are entirely satisfactory. Owing to foot-and-mouth disease an embargo has been placed on pork imported from the Netherlands; as a result, the Irish Free State, the U.S.A., Argentina, and South Africa have increased their shipments. Caseous lymphadenitis is being noticed more frequently in sheep carcasses, and Dr. Howarth suggests that it should be made an offence to cut out lymph glands from mutton and beef, as it is at present n the case of pig carcasses. The Argentine and the Australian governments are both investigating the prevalence of this disease and have given instructions that no meat with glands cut out is to be exported. A considerable number of carcasses and heads of pork are condemned for tuberculosis. It is generally assumed, says Dr. Howarth, that the bacilli are of bovine origin, but inquiries made of the owners of diseased pigs show that frequently the animals have not been fed on cow's milk or been in contact with cows. The suggestion is put forward that the pigs may have been infected by fowls and that a pathological investigation to discover whether pigs may be infected with the avian bacillus might be useful. Slaughtering at Aldgate, which has been carried out for hundreds of years, ceased with the close of 1926. It is usual to examine about 50 samples of milk for tubercle. During 1926 the City bacteriologist, Sir Frederick Andrewes, reports that for the first time no tuberculous milk was found among the samples taken. The number of samples satisfactorily examined was only 34 owing to the premature death of some of the guinea-pigs. Under regulations dated 1926 importers of milk are required to register with the local authority, but no such importers have as yet been registered in the City. Progress is being made with the closure of houses in the Hutchison-street and Vine-street insanitary areas, and provision of accommodation for the displaced tenants is now well advanced.

The proportion of deaths in the City caused by injuries and violence was 2·3 above the average for the previous five years. The percentage was 7·2 in 1926, 5·3 in 1924, and 4·4 in 1925.

A suggestion has been put forward that a convalescent home might be established for the benefit of

the maternity and child welfare committees of the metropolis. Dr. Howarth points out that the charities peculiarly associated with the City make participation in such a scheme unnecessary.

Endeavour was made during the year to solve one of the difficulties of the tinned fruit trade. It is occasionally found that the tins are "blown," although the fruit inside is in perfectly good condition. These tinned products are sealed whilst hot, with the result that the ends of the container become concave on cooling. Several tins, the ends of which had become convex, were examined by the bacteriologist, who found that the contents were quite good to eat and that there was no evidence of bacterial action. The City analyst also examined them and thought that the "blowing" was due to a slight alcoholic fermentation. The circumstances have been reported to the Ministry in the hope that the matter will be further investigated.

Rat repression goes on actively. Dr. Howarth thinks that the number of rats is being kept down, but says that the old English black rat is now three times as numerous as the brown sewer rat. Old City men state that 30 or 40 years ago they were unable to enter their office in the mornings until the rats had been cleared out; these were brown rats, which had practically exterminated the black rats. The black rats now have their chance because the brown rats are being reduced by poisoning and trapping, and the overhead travelling facilities, by electric cables and the like, have been greatly increased for the black rat, who is a wonderful climber. The black rat needs less water than the brown rat and can generally find enough for his needs at sinks, dripping taps, fire buckets, and uncovered closet pans. If all food and water were adequately protected the rat trouble would largely disappear. In support of this it has been stated that Leicestershire mines are free from rats and mice for the first time in the memory of the oldest pitman, due to starvation caused by the coal strike.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Wigan ..	13,743	12,283	4,379	9,547	21·0
Hull	46,975	39,933	15,526	10,200	10·5
St. Helens .	20,357	18,303	5,984	13,602	44·17

* Excluding uncleanliness and dental defects.

Wigan.

The established position of the clinic as a necessary part of public health work is shown by Dr. H. Whitehead's insistence that the new tuberculosis dispensary (shortly to be erected) should also contain a dental department, an orthopædic clinic, a laboratory, and a section for artificial sunlight and X ray treatment. Children up to 5 years of age come under the maternity and child welfare scheme, and from that age pass under the school medical service with a direct continuity of their preschool records. During the year many sanitary improvements have been made in the schools and there is now only one school with pail-closets.

The compulsory notification of chicken-pox has laid an extra strain on the service, since every case was visited by a medical officer and subsequently by a school nurse, who also visits cases of measles, mumps, whooping-cough, and influenza. From the list given of the periods of exclusion from school for cases and contacts of infectious diseases it would seem that these periods are longer than obtain in most places. A table shows the percentage of verminous children in the schools to vary from 6 to 39; healthy rivalry might help to reduce this high figure.

Playground classes are held in some schools, and during last summer a school camp was established in which 701 boys and girls spent one week under canvas. Dr. Whitehead puts forward an eloquent case for an open-air school, and points out that there are 1200 children in Wigan in urgent need of such treatment. Although there is no organiser of physical training, games and sports are encouraged. The arrangements for an orthopædic scheme are now completed and will shortly come into force. Attention is called to the inadequacy of provision for exceptional children.

Hull.

Dr. W. Allen Daley pays a generous tribute to the late senior medical officer, Dr. J. Fraser, for his "sound conception and careful nurture" of the school medical service in Hull. The report, written by Dr. J. Morrison, formerly of Bristol, admits the slowness of progress and states that the Education Committee is beset with difficulties, not the least being the lack of funds. Myope classes were suggested by Dr. Fraser as far back as 1911, the possibilities of an open-air school were discussed in 1912, and several years ago the use of X rays for ringworm was recommended; but none of these things is yet in being. The need for more dental staff is pressing; the proportion of fillings to extractions stands at 1 to 10 for Hull, compared with 1 to 3 or 4 in the country generally. Ignorance and apathy on the part of the parents are contributory factors. Extra nurses also are badly needed.

The Hull authority have in their own deaf school an example of a wise expenditure yielding excellent results; a natural corollary would be the appointment of an aural surgeon to supervise and assist the work of the school; by the early detection of aural defects handicaps which materially reduce earning capacity might be largely eliminated. The craft classes are doing good work and have been increased, but, as the report states, "the masking of mental deficiency by means of dull and backward and craft classes would not appear to be desirable. Craft classes can be extremely useful as a means for observing doubtful cases and as an intermediary between the ordinary school and the special school both before and after a stay in the latter type." The great necessity is for closer medical investigation of the children concerned; this point is of wide general application, for dull and backward children are also, in a large proportion of cases, physically defective. From every point of view it is essential that they should be under special medical supervision.

This report, as for many years past, makes interesting reading.

St. Helens.

The large percentage (44·2) of defects found in the school-children does not necessarily mean that the general standard of health is lower in St. Helens than in other comparable areas, but rather indicates the adoption of a stricter standard by the inspecting medical officer; for example, 23·9 per cent. of the children examined were noted as having tonsils and adenoids, though only 1·6 per cent. were referred for treatment. In his detailed lists of treatment carried out from 1921–26, Dr. Frank Hauxwell shows how the ordinary school-child is looked after and how defects are treated, but the report indicates also how much the exceptional child is neglected, and its main theme is a well-reasoned plea for the provision of facilities to treat this type of child. The new orthopædic scheme was inaugurated on Oct. 1st and already 40 children have been treated. The immediate urgent needs are for: (*a*) Extension of dental inspection and treatment to include all school-children. (*b*) An open air school. (*c*) An additional clinic for minor ailments and dental defects. (*d*) A special school for cripples. (*e*) Provision for the partially blind. (*f*) Provision for the cardiac cripple. The supply during the year of 2,061,093 school meals, of which 2,053,228 were provided free, scarcely masks the lack of treatment facilities apparent from a perusal of Dr. Hauxwell's report.

THE LANCET.

LONDON, SATURDAY, JULY 9, 1927.

RESPONSIBILITY FOR CERTIFICATION OF THE INSANE.

THE law relating to the responsibility of the medical practitioner for the certification of an insane person cannot be left in its present deplorable state of uncertainty. There is a pleasant maxim or fiction of English jurisprudence that everyone is supposed to know the law, or at any rate that no one is to be excused for not knowing it. Mr. Justice MCCARDIE has made it clear, when giving judgment in DE FREVILLE *v.* DILL, that one of the most careful and learned judges of the Supreme Court is in doubt of the legal principles applicable to the doctor who certifies a lunatic. He expressed the hope that before long the House of Lords would give a clear and final decision upon the two outstanding points of uncertainty. Each of them, he said, was a matter of grave importance both from a legal and a practical point of view. It is indeed regrettable, as Mr. Justice MCCARDIE remarked, that so great a difference of opinion should exist and that a judge at trial should be beset with difficulty and doubt for want of knowing which of the previous decisions he should follow For the medical profession the incertitude is paralysing; its members are embarrassed by exposure to an indefinite personal liability.

The two points at issue, familiar though they are, may be briefly stated once more. The first is the question whether a medical practitioner, when summoned to express an opinion upon the sanity or insanity of a person, owes to that person any duty in the legal sense to exercise care. Dr. DILL was called in to examine Mrs. DE FREVILLE at the instance of her husband or her father-in-law. Mrs. DE FREVILLE did not call him in; she never employed Dr. DILL; she made no contract with him nor did she ever consent that he should act as her medical adviser. Dr. DILL, in examining her and forming his opinion, was acting on behalf of others, not on her behalf. Does a doctor in such a case owe any legal duty of care to the person he examines? It is amazing to find that, although this question stands upon the threshold of such litigation and has frequently been discussed in the past few years, there is no clear answer thereto in any judgment by the final appellate tribunal. Mr. Justice MCCARDIE had to approach the question without the guidance necessary. It is plain that a surgeon who operates negligently on the body of a patient is liable in damages, though there is no contract between the patient and himself. So, too, is the physician who is negligent in giving the patient medicine. Dr. DILL performed no operation and gave no medicine. He merely discharged the rather unwelcome function of intervening between members of a family and expressing an entirely honest opinion that Mrs. DE FREVILLE was a person of unsound mind and a proper person to be taken charge of and detained under care and treatment. On the whole, Mr. Justice MCCARDIE came to the conclusion that the balance of legal authority leaned towards the principle that Dr. DILL did owe Mrs. DE FREVILLE a duty of care. The second question is whether the medical practitioner's certificate is the cause of the certified person's detention. As is well known, the machinery of the Lunacy Act interposes between the certifying doctor and the person certified a vital link without which the person cannot be detained as a lunatic—namely, the judicial consideration of the evidence by a magistrate who, after satisfying himself that the evidence is sufficient, orders the detention. Mr. Justice MCCARDIE definitely states that, in the absence of other legal authority, he would have thought that the effective cause of Mrs. DE FREVILLE'S detention was the order of the magistrate and not the certificate of Dr. DILL. The decision under the Lunacy Act lies with the justice, not with the doctor. The justice can decide as he pleases, whatever the certificate says. Parliament has invested him with a statutory judicial authority in addition to the ordinary jurisdiction of his ancient office. He has full discretion, and he adjudicates *pro tempore* upon the matters placed before him. The doctor's certificate, though an essential requirement, is a mere opinion which of itself possesses no operative force. But here again, after endeavouring to weigh against one another the conflicting views of earlier judges, Mr. Justice MCCARDIE inclined to consider that he was bound by the greater weight of authority to decide against Dr. DILL, though he added that he doubted whether the full effect of the recent case of HARNETT *v.* BOND had been adequately realised.

In reaching, evidently not without misgiving, these two conclusions adverse to Dr. DILL, the learned judge made no attempt to disguise their seriousness to the medical profession. The passage in his judgment which dealt with this aspect calls for the immediate attention of Parliament. During the past seven years, he said, many medical men, acting in perfect good faith, have been exposed to the most prolonged, harassing, and costly litigation on the allegation that they have acted without reasonable care in a matter which is the most difficult, delicate, and indefinite in the whole range of medical practice. It may well be that, as the result of past litigation, many doctors have refused, and will refuse, to take any part whatever in the work of certification because of the perils and anxieties of litigation which may follow. In suggesting that some further protective legislation is needed, the learned judge gave judicial confirmation to views expressed from time to time in these columns. The same views have been uttered in other places where the interests of the medical profession are by no means paramount—for instance, in the House of Lords during the debate upon Earl RUSSELL'S motion some months ago. The Lunacy Act machinery for the certification and detention of the insane was not devised or created to gratify doctors but to protect the public and to benefit the mentally afflicted. The machinery cannot be worked without the medical profession's assistance. If that assistance is to continue, safeguards must be furnished; and if the highest judicial tribunal will not positively state that these safeguards exist, Parliament must forthwith provide them.

THE METHODS OF BESREDKA.

FOR some years Prof. A. BESREDKA, of the Pasteur Institute, Paris, has been putting forward suggestions which are in definite opposition to current teaching about the nature of immunity. Following upon the work of METCHNIKOFF, PFEIFFER, BORDET, EHRLICH, and a veritable host of other investigators and teachers, two main theories have been developed—the cellular, whose parent was METCHNIKOFF, regarding resistance to infection as primarily the work of

the leucocytes and their ferments, and the humoral, begotten largely of the German school, emphasising the importance of the body fluids and the phenomenon of bacteriolysis. The battles of long ago resulted in an agreed peace, and the modern student has been brought up to believe that immunity is governed by both of these influences. But it must be admitted that our knowledge is incomplete and our explanations unsatisfactory; no worker in this field, if he has a critical sense, can feel complacent about their sufficiency. Part of the confusion may be due to the fact that immunological research has opened up so many paths for investigation, and has produced so many useful by-products in the way of clinical tests, that the main issue has been clouded in the complexities introduced by elaborate technique. It is the merit of more recent workers, and of BESREDKA in particular, that they have once again drawn attention to the main problem of the antagonism between the living body and the invading organism.

The earlier and more important of BESREDKA'S theses is now generally known. The body defends itself, he considers, not so much by a general reaction common to many tissues, as by a local reaction in the tissue which is primarily the seat of disease and through which the organism normally gains entrance. This tissue, different in different diseases, he regards as both susceptible to invasion and capable of acquiring an immune state, a theory which has been mainly based on the phenomena of infection by anthrax, in which disease, it is held, it is essential that the skin shall first be invaded if infection is to occur. Experiments have been produced and multiplied which go to show that if anthrax bacilli be introduced into the body without infection of the skin the animal will survive their attack. Conversely no immunity results from infection which avoids the skin, whereas "solid" immunity can be given to animals—and even, apparently, to such susceptible creatures as the guinea-pig—if the virus is applied to the skin in such a way as to produce a mild local lesion. Such ideas present a point of view somewhat fashionable in France at the moment, finding an echo in LEVADITI'S contentions about the "neurotropic dermatoses," and their logical extension suggests that immunity to superficial and septic infections can be secured by dermal inoculation, whilst resistance to typhoidal and dysenteric disease is to be sought through local immunisation of the intestinal mucosa with vaccines given by the mouth. In connexion with this subject attention may be drawn to some extremely interesting observations made by D. B. BLACKLOCK and R. M. GORDON upon an allied phenomenon in metazoal infections, and recently described in our columns.[1] They found that in animals experimentally infected with larvæ of a fly, *Cordylobia anthropophaga*, which can penetrate and exist in the skin, giving rise to boils, a definite degree of immunity follows upon a first infection. This appears from their experiments to be an example of tissue immunity localised in the skin and most pronounced in the area in which the initial infection was produced, although diffusing to the rest of the epidermis. Our knowledge of immunity in metazoal infection is so fragmentary that this contribution deserves grateful attention. At the same time, as the authors state, there is some indirect evidence that the immune state, even if conferred by the skin, may be dependent upon the general metabolic exchanges, since grafts of skin from a susceptible individual eventually become immune when implanted in the body of a resistant animal.

[1] THE LANCET, April 30th, p. 923.

BESREDKA'S stimulating suggestions on immunity are not his only contribution to current thought, for he appears also as the ardent advocate of an entirely new method of bacterial therapeusis. He maintains that the cessation of growth in bacterial cultures is not due to any exhaustion of the pabulum available—as is generally supposed—but rather to the production of an "antivirus" inimical to the organisms' continued growth. This view, which fits in well with the experiments on which MARMOREK founded his belief in the unity of the streptococcal species, has suggested a possible means of treatment. In superficial infections, such as those caused by the pyogenic cocci, he recommends the use of dressings soaked in filtered cultures, and it is said that excellent results have been obtained. The opinions which we have here briefly summarised are expressed at length in a monograph on local immunisation, written by BESREDKA and recently translated into English.[2] In it the bacteriologist and the student of medicine in its broad aspect will find an abundance of novel ideas with a strong infusion of commonsense. He will also find much that is slipshod and uncritical, but this does not mean that the claims do not deserve careful examination and independent repetition, by which alone their worth can be decided.

SCIATIC PAIN.

AMONGST painful diseases sciatica occupies a foremost place, by reason of its prevalence, of its production by a great variety of conditions, of the great disablement it may produce, and of its tendency to relapse. These have led to its recognition as one of the great scourges of humanity. It was in these words that Prof. VITTORIO PUTTI introduced his new conceptions in the pathogenesis of sciatic pain when delivering the Lady Jones Lecture at Liverpool a few weeks ago.[3] This lecture appears at length in our present issue. Prof. PUTTI'S unparalleled experience at the Bologna Orthopædic Institute, of which he has charge, and his great reputation as a technician will ensure a respectful hearing for unfamiliar views. Continental writers, it has been recently remarked,[4] lay great stress on the association of spinal arthritis with sciatic neuritis; the occurrence of bony union between the transverse processes of the fifth lumbar vertebra and the sacrum, known abroad as sacralisation, has been credited with a great variety of painful affections of the lower limbs. Dr. HENRI DUFOUR, of the Hôpital Broussais, brought some of these cases last month before the Paris Medical Society of Hospitals[5]; in them there was not only fusion of the last lumbar vertebra with the sacrum, but the twelfth rib was missing, an observation which he would like others to note and confirm. Dr. DUFOUR is inclined to regard sacralisation as by no means a rarity, although it will be seen that Prof. PUTTI does not regard it as a frequent or potent cause of sciatica. The last lumbar vertebra is on the Bologna showing very liable to congenital variation; the foramen between it and the sacrum is the smallest of the series of openings transmitting spinal nerves; the vertebra itself is exposed more than any other to

[2] Local Immunization. By Prof. A. Besredka, Pasteur Institute, Paris. Edited and translated by Dr. Harry Plotz, Pasteur Institute, Paris. London: Baillière, Tindall and Cox. 1927. Pp. 181. 16s.

[3] THE LANCET, March 12th, p. 557.

[4] J. H. Anderson, Ibid., April 16th, p. 837.

[5] Bull. et Mém. de la Soc. Méd. des Hôpitaux, June 23rd, 1927, p. 922.

the sort of compression and strain which may set up arthritic processes. Herein, according to Prof. PUTTI, lies the explanation of the frequency of nervous involvement in this region. We are not aware of any extensive X ray examination of such cases in this country which would throw light on the Bologna findings, but marked changes have often been found on palpation of the muscular and fibrous tissue attached to the spine long before any bony change has become apparent on the X ray screen. In another region of the spinal column, Dr. HENRI FORESTIER, of Aix-les-Bains, recalls attention to the nodules and thickenings, frequently found in the neighbourhood of the cervical vertebræ in patients complaining of chronic headache and neuralgic pains, described many years ago by Prof. R. STOCKMAN, of Edinburgh. It should prove possible by some special method of screening to demonstrate changes such as these on the radiogram. Spondylitis, when clearly marked by bony change visible on the screen, is already a late stage in the condition. Whatever may be its earliest manifestation —and much more study of the subject is required before a definite opinion can be given—the work at the Bologna Institute is instructive in explaining how vertebral abnormality may cause pressure on nerves in the intervertebral foramina. But the question still remains, Is this pressure sufficient in itself to produce sciatica? Prof. PUTTI seems to hold that the congenital abnormality produces arthritis which in turn leads to sciatic pain, but he does not make it quite clear whether the congenital abnormality may be present without giving rise to arthritis. Clinicians in this country are familiar enough with cases of spinal arthritis in which the evidence of spondylitis is convincing but in which no pain is referred to the endings of the sciatic nerve. It seems likely that in addition to the congenital abnormality which Prof. PUTTI demonstrates so clearly there is a superadded factor of infection somewhere in the body, for there is evidence that removal of a chronic source of infection may cure sciatica even though the spinal arthritis persists. In recalcitrant cases, however, the publication of Prof. PUTTI'S experience should certainly lead to a trial of the treatment which he recommends—namely, active hyperæmia with mobilisation of the lumbar spine.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Dr. A. C. Roxburgh will give a special demonstration at the In-Patient Department of St. John's Hospital for Diseases of the Skin (262, Uxbridge-road, London, W. 14), on July 12th, at 2.30 P.M. On July 15th, at 5 P.M., Mr. G. Viner will give a lecture on Epiphora at the Royal Westminster Ophthalmic Hospital; and on the same date Mr. Archer Ryland will demonstrate at the Central London Throat, Nose and Ear Hospital at 10 A.M. Those desirous of attending this latter demonstration are asked to notify the hospital—Museum 1539. All these demonstrations are free to members of the medical profession. From July 11th to 16th the St. Mark's Hospital staff will undertake a special course occupying six afternoons and three mornings, and including lectures, operations, X ray and pathological demonstrations. Also beginning on July 11th is a two weeks' vacation course at the Prince of Wales's General Hospital, Tottenham, which will include instruction in medicine, surgery, and the specialties. The formal lectures at 4.30 P.M. are open to members of the Fellowship of Medicine. A four weeks' course in neurology at the West End Hospital started on July 4th, consisting of lecture-demonstrations at 5 P.M. daily. From July 13th to 30th a course in infectious fevers will be held at the Park Hospital, Hither Green, S.E. Instruction will be given on Wednesdays at 2.30 P.M., and on Saturdays at 11 A.M. Two special courses will take place in August—one on Diseases of Infants at the Infants Hospital, from August 8th to 20th, and one on Medicine, Surgery, and the Specialties, at the Queen Mary's Hospital, from August 29th to Sept. 10th. A general course of work, for which a separate programme is issued, is also provided by the Fellowship at the associated hospitals. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Fellowship of Medicine, 1, Wimpole-street, London, W.

Annotations.

"Ne quid nimis."

THE "CHEMIST AND DRUGGIST."

WE offer our congratulation to the *Chemist and Druggist* on the production of a special number (June 25th, 1927) which can be described as a triumph of trade journalism. Not even in the United States of America, where they do these things so well, do they produce anything better than this; and when we consider that this large volume—too large to be sent through the post—was delivered to its subscribers at almost the usual time on the ordinary day of publication, and this without impairing the up-to-dateness of its market news, we think the editorial staff, the printers and publishers have done something of which they can be justly proud. The *Chemist and Druggist* was, we believe, one of the first, if not the first, trade paper to be produced in this country; there were, of course, scientific and professional journals in being a considerable time before our Cannon-street contemporary issued its first number, as for instance (not to mention ourselves) the *Pharmaceutical Journal*, which at that time, if our recollection is right, was devoted almost entirely to the scientific side of pharmacy. To the *Chemist and Druggist*, however, belongs the honour of being a pioneer of trade journalism. We understand that this special number synchronises with the retirement from the editorial chair of Mr. S. W. Woolley, who has been editor of the *Chemist and Druggist* for some ten years; in this his final contribution to the chemists' library he has certainly left behind him a monument. Mr. Woolley has, we believe, for many years been a student of times past, and from time to time has given his readers the benefit of his searches in old book shops and libraries and museums both at home and in continental countries. Evidence of the patience and diligence with which he has pursued his hobby is to be found in some of the articles in his last special number. For instance, there is an historical sketch running to some 12 pages, the illustrations, as well of course as the text, in which will no doubt be preserved by every chemist who receives a copy of the paper. There are, for example, reproduced in colours four vellum leaves from the beautiful MS. prepared at Constantinople in 512 A.D. for Juliana Anicia, daughter of the Emperor Flavius Anicius Olybrius. Then, again, the Arabesque border on the first page of the article is from a page of the Galen MS. at Dresden. Indeed, the paper abounds with reproductions of priceless frontispieces: volumes in the Vatican Library, the British Museum, the National Library at Turin, and so on have been utilised by the block maker in a most skilful way. This is only to mention one section of the number; equally worthy of perusal are the illustrated article on the metal utensils used by the ancient druggists and the entertaining, not to say amusing, anecdotes about the quacks of old.

THE INHERITANCE FACTOR IN TUBERCULOSIS.

THE detailed schedules of over 4000 consecutive patients who first attended the tuberculosis institutions in the City of Belfast from 1914 to 1917 are the material from which Dr. Percy Stocks, inspired by Prof. Karl Pearson, has compiled a study [1] of the inheritance factor in tuberculosis. Dr. Stocks has deduced rates of active tuberculosis among brothers and sisters of those tuberculous patients by sex and age-groups; the ages of non-tuberculous brothers

[1] Fresh Evidence on the Inheritance Factor in Tuberculosis. By Percy Stocks, M.D., Medical Officer, Galton Laboratory, University of London. From Annals of Eugenics, vol. ii., Parts 1 and 2, April, 1927. Cambridge University Press.

and sisters were not always available, and for ages over 10 it was assumed that the proportionate age distribution of brothers and sisters was the same as that of the patients themselves. The next step was to estimate comparable rates for the general population in Belfast. Here, again, certain assumptions had to be made to fill in gaps in the data—e.g., that the ratio of deaths to active tuberculosis cases was the same in the whole of Belfast as in the dispensary population. From these rates it appears that tuberculosis of all forms was more prevalent among females than males in the ratio of about 3 to 2; the maximum prevalence in both sexes appeared to be at the school ages, but the fatality was much lower at this period than at any other. At ages under 20 in both sexes the prevalence of active tuberculosis among the living brothers and sisters of the patients was notably higher than in the general population. A more comprehensive estimate was then made by computing on a life-table basis the total numbers at any age, living or dead, who had been previously attacked, and whether the disease was active, latent, or cured. Again, the data were not complete and assumptions had to be made to estimate the numbers "surviving cured." The resulting smoothed curves showed that the total rate of onslaught was greatest in the first seven years of life in both sexes, and from 15–25 in females, and to a less extent from 20–30 in males. In the first of these periods the mortality curves do not show a corresponding steepness. Dr. Stocks estimated for every age the correlation between the incidence in pairs of brothers and sisters, obtaining at all ages after 10 a fraternal correlation of the order 0·25 to 0·3. During the first 10 years of life the association was higher.

As to the relative parts played by heredity and environment, the author lays more stress on the former than the latter, as he considers that if environment acted alone there would be a consistent tendency (which does not appear in the results) for these correlation to decrease regularly after 10 years of age. He points out, however, that the correlation in the first ten years of life is rather higher than would be expected from heredity alone, and suggests that this may be due either to direct infection among young children or a common source of infection, or possibly to the tendency for the tuberculosis officer to have all the brothers and sisters of a young tuberculous child examined, those of school age being more easily accessible than the older ones. It is hard to escape the feeling—and this is to the credit rather than the disparagement of the author—that if the reader begins with doubts he will end with doubts, and if he begins with certainties he will end with the same certainties.

INSULIN IN THE TREATMENT OF MALNUTRITION.

CERTAIN American observers have used insulin in marasmic infants and in debilitated and emaciated adults and those convalescent from various ailments with gratifying results. Recently, Prof. E. Trocello, of Rome, has described the results of 18 cases in a paper read at the Medical Congress at Padua last year, which has recently been published.[1] It should be recalled that Falta, of Vienna, in July, 1925, drew attention to the results obtained by insulin in three emaciated subjects in whom treatment by rest and superalimentation had failed. A rapid and enormous increase of weight occurred. The method adopted by Dr. Trocello is as follows. Every day, with the exception of Sunday, an injection of insulin is given one hour before lunch and dinner simultaneously with a drink containing 50 g. of sugar. The dose administered was 10 to 25 units in accordance with the tolerance of the patient, any hypoglycæmic disturbance being watched for. Out of the 18 young women treated the insulin was discontinued in four cases, one for hypoglycæmic disturbance, two owing to slight fever, and one on the development of tuberculosis. In the remaining 14 cases the results obtained were as follows. At the end of the treatment, which lasted about a month, there was an average gain of weight of 2·00 kg. A month after the termination of treatment an average increase of 2·07 kg. was maintained; in seven cases the increase had diminished, in seven it was intensified. Three months later the mean increase was 2·31 kg. In all cases the weight was above that observed before treatment. During the treatment in nearly all the cases the appetite became enormously increased; in the majority there was a sense of well-being and marked improvement in the neurasthenic symptoms, such as headache, giddiness, tachycardia, and constipation. After four months from the cessation of treatment seven cases were completely cured, marked improvement had taken place in two, some improvement in one, partial relapse occurred in two, and total relapse in one.

THE PLAGUE PROBLEM IN SOUTH AFRICA.

PREVIOUS to 1899 there is no record of the occurrence of plague in the Union of South Africa, though it must have been frequently introduced from India it does not appear to have spread. During the South African War, however, plague found its way to the territory now incorporated in the Union from the Portuguese port of Lourenço Marques, and spread inland. In February, 1901, a plague epizoötic occurred in Cape Town docks where large stores of grain had accumulated, and since this time the disease has become endemic and given rise to considerable anxiety. These and other historical details are recorded in a recent publication of the South African Institute of Medical Research (No. XX., Vol. III., pp. 85–256) on the Plague Problem in South Africa by Dr. J. Alexander Mitchell, Secretary for Public Health and Chief Medical Health Officer for the Union of South Africa, Dr. J. H. Harvey Pirie, and Dr. A. Ingram, who are attached to the Institute respectively as pathologist and medical entomologist. During the years 1916–20 the sporadic prevalence of plague in the midland districts of the Cape, in localities where no direct contact with persons infected could be traced, puzzled the authorities. In 1920, from the study of all available information, it was found that the distribution of the outbreaks corresponded with areas or sandy stretches in which the gerbille (*Tatera lobengulæ*) was especially prevalent. Suspicion was therefore aroused that the multifarious rodent fauna of the veldt was acting as a reservoir of plague infection. Soon, in February, 1921, convincing proof was obtained in the death of a farmer near Bothaville, and in the vicinity an extensive plague epizoötic in the gerbilles and multimammate mice was thereby disclosed. Excavation of the burrows and the discovery of numbers of recently dead and dying mice left no doubt on this point. Subsequently more abundant proof was obtained and other rodents, such as the large-eared mouse, the striped mouse, and ground squirrel were found naturally infected. Public attention was riveted on this subject during the extensive epidemic of plague in the Orange Free State in 1923–24. The total number of cases was 329 with 204 deaths; all except six of these cases occurred on farms, and native herd boys were most frequently attacked. In most instances infection was traceable to veldt rodents and about 12 per cent. of cases were pneumonic in type. A virulent rodent epizoötic preceded and accompanied the epidemic. In some localities the carcasses of veldt rodents could be collected by the barrow-full, and it is estimated that 90 per cent. of these creatures had died. The larger rodents, such as the karoo-rat, spring hare, black rat, house mouse, and mongoose were also victims. Fortunately for the prevention of the spread of plague, the veldt rodents are such shy animals that they seldom travel by rail and that, with the exception of the multimammate mouse, they rarely enter the dwellings of man; evidence of the reimportation of plague

infection from the back veldt to Cape Town has so far been lacking. Another very fortunate circumstance is that the species of fleas infesting these veldt rodents are rarely found on the more domestic species or vice versa, so that infection does not travel from one to the other as readily as might have been expected. So far as is known, there has been no plague in domestic rodents in the Union since the Durban outbreak in 1912. Extensive research into the susceptibility of the veldt rodents to artificially inoculated plague has been carried out and showed that with the exception of one species (Namaqua gerbille) all succumb readily to the infection. The work has embraced extensive zoological studies of the ætiology of the veldt fauna as well as of their flea parasites by Dr. Ingram. Some useful practical information has emerged, such as the observation that the yellow mongoose and the suricate feed only on gerbilles when they are sick of the plague, so that the appearance of the fur of these animals in their excreta affords a valuable index of the prevalence of rodent plague in the district. The work has also resulted in the discovery of a hitherto unknown epizoötic disease in gerbilles locally known as the "Tiger River disease" due to a small Gram-positive bacillus—*Listerella hepatolytica*. Field experiments contributed by Dr. Pirie suggest that plague infection can only be kept alive in a scanty rodent population by flea transmission. The report is well illustrated by a coloured map of the Union showing the known distribution of rodent plague, as well as by a number of photographs of the various species of small mammals concerned.

OVARIAN GRAFTS.

STIMULATED by the good results obtained by Voronoff and others by means of testicular grafts obtained from the male monkey, Dr. Latis, gynæcologist to the Israelite Hospital at Alexandria, has applied the same method to the female taking his grafts from the female monkey. The patient, whose case he describes,[1] was 30 years of age and had suffered for some ten years from dementia præcox associated with signs of ovarian insufficiency. She had mental hallucinations with paroxysms of mania. The grafts were implanted on the surface of the ovaries themselves; the laparotomy which this course necessitated had the advantage of allowing an examination of the patient's own ovaries. These were found to be fibrotic and cystic. The operation was followed by the reappearance of the menses and by a marked diminution in the intensity of the patient's hallucinations, with corresponding improvement in her mental condition. There was also an increase in the size of the breasts. Dr. Latis adds to the description of his own case accounts of several operations carried out by other surgeons employing grafts either from a monkey or from other patients on whom an oöphorectomy had been performed. He mentions a patient of Mauclaire's in whom an ovarian graft was reported to have survived for a period of over eight years. He draws the conclusions that there exists a definite sphere of utility for ovarian grafts in gynæcological surgery, and states that good results may be obtained from the use of autografts, homo- or homeo-grafts, by the last named being meant grafts obtained from an allied species—namely, in the case of man, the higher ape.

Interesting though Dr. Latis's case undoubtedly is, we find his conclusions too optimistic. Many surgeons during the last decade have attempted to remedy ovarian deficiency by means of the implantation of human ovaries, and have failed to achieve any results. Blair Bell reports that he has failed to obtain any benefit from the use of homografts, although better success may follow the employment of an autograft. Even if improvement in the patient's condition be noted by the use of a homeograft it is probable that this is not due to vascularisation and survival of the implanted tissue, but to the absorption of a certain amount of internal secretion whilst it is breaking down. It is an unfortunate fact that the use of grafts in human beings gives far less favourable results than in the case of the lower animals. It is impossible to read the description of Steinach's experiments on guinea-pigs and rats without being deeply impressed, but when similar methods are employed in the human species the experiment usually turns out a failure. For some at present unknown reason the grafting of the more highly organised tissues on a human being is unsuccessful. Where apparent success is obtained it can generally be explained by the absorption of internal secretion during the process of degeneration of the graft.

INTERNATIONAL MEDICAL HYDROLOGY.

THE International Society of Medical Hydrology will hold its annual meeting in Rome from Wednesday, Oct. 12th, to Monday, Oct. 17th, under the hon. presidency of Sign. Mussolini, the President-Elect being Prof. Gabbi, of Parma. At the opening session in the University building Prof. Strasser, of Vienna, will open a discussion on the Uses of Water in Acute Disease, after which members will take part in the official opening of a new State bath establishment at Montecatini. Papers will be read on the Biological and Physical Properties of Medicinal Waters, on their Effect on Immunity, and on their Action on Ferments. The list of speakers includes Profs. Valenti, Marfori, and Chassevant, Drs. Mougeot, Ferreyrolles, and Burt, Messrs. Woodmansey and Race. Prof. Zörkendörfer will speak on the Processes of Change in Medicinal Waters, and Dr. Judd Lewis will bring forward proposals for International Standards of Analysis and Measurement. The Society is also invited to Salsomaggiore, and may have an opportunity of visiting the University of Parma. More than 100 names of members and their friends have been already inscribed for the tour, but the list is still open, and the Council will welcome the presence of medical non-members interested in the objects of the Society. Reduced fares and other privileges are offered to the party. Application should be made to the Hon. Sec., I.S.M.H., 139, Marylebone-road, London, W. 1.

ANTERIOR PARATHYROIDS.

SINCE the advances of surgery and of endocrinology combined to make operations on the thyroid a matter of common occurrence, it has become important for surgeons to know the exact anatomical position of the parathyroids. Their classical situation is on the posterior aspect of the thyroid lobes at the junction of the middle and upper third and in the lower third respectively. Several observers have recorded variations. They may be fewer or more than four, and small accessory fragments may lie scattered throughout a wide area. W. G. MacCallum [1] found inferior parathyroids at or below the lower pole, or even behind the trachea or in the thorax. E. H. Pool [2] found one on the front of the isthmus. In a recent issue of the *Canadian Medical Association Journal* [3] Mr. R. J. Millzner records the results of a careful search of all thyroids removed at the University of California Hospital. The parathyroids were usually found quite easily by following up the branches of the thyroid arteries, along one of which they almost invariably lie. They were recognised by their soft flabby consistency and yellowish or pinkish brown colour, as well as by the prominent artery entering the hilum. The percentage found rapidly increased with the development of skill in their detection, and at the peak it was manifest that parathyroid tissue was removed in 28 per cent. of all thyroidectomies. After that the technique was modified in order to reduce the percentage. Of those removed a very large number were on the anterior aspect of the lobe or isthmus, and the alteration in technique, which involved leaving the

[1] Brit. Med. Jour., 1906, ii., 1282.
[2] Ann. Surg., 1907, xlvi., 71.
[3] Can. Med. Assoc. Jour., April, 1927, xvii., 1053.

lateral part of the front of the capsule behind, saved about two-thirds of these. It is now the custom of the California Hospital to have the pieces of thyroid removed searched in the theatre; any parathyroid tissue discovered is implanted in the sternomastoid muscle by Lahey's technique at the conclusion of the operation. The author is uncertain whether these anterior parathyroids are accessory, or normally or atypically located parathyroids, or whether they were originally posterior and have been displaced. On the whole, he concludes that the anterior site is a normal variation and autopsy material has confirmed this. If approximately 10 per cent. of parathyroids lie in front of the thyroid gland while 30 per cent. lie on its lateral surface, it is clear that the recognition of the less common position is of primary importance for the operating surgeon.

"TENNIS LEG."

WE are not familiar with the term "tennis leg" in this country, but in America the term seems to be in current use as a name for a group of injuries which are characterised by more or less damage to the muscles, tendons, and aponeuroses forming the triceps cruris. Under it are also included injuries caused by violent strain of the plantaris. Such injuries and their successful treatment have been well known for many years. A noted case is that of the Edinburgh surgeon and anatomist, Alexander Monro primus, who died in 1767. In his Collected Works [1] will be found a description of his case and of the means which he successfully employed for its cure. A few years ago a distinguished Welsh surgeon suffered a similar injury and described his case and cure. Monro's injury was rupture of the whole of the tendon of Achilles, whereas "tennis leg" is usually a less complete and serious lesion, involving generally only some fibres of the soleus or gastrocnemius or the plantaris tendon. In a recent number of the *Medical Journal and Record*,[2] published in New York, Dr. F. Christopher advocates early mobilisation (with avoidance of violent exercise) in cases of this injury, and records good results. It is interesting to find that after a fortnight's fixation in full plantar flexion, Monro practised active movements and that he stated that his recovery was complete, which it had not been in all of the 16 other cases which he had seen. There can be little doubt, we think, of the benefits to be obtained by massage and heat and early or immediate gentle movement in the slighter cases of this not uncommon lesion. Dr. Christopher does not refer to the use of a high-heeled boot which has been very generally recommended during the early stages of treatment and which was used by Monro.

THE CAUSATIVE ORGANISM OF TRACHOMA.

Dr. Hideyo Noguchi has succeeded in isolating from the trachomatous conjunctiva of man an organism which produces follicles followed by scarring when injected beneath the conjunctiva of chimpanzees. The organism was recovered from the follicles and cultured, when it again produced the same results on inoculation. The announcement was made at the recent annual session of the American Medical Association, when the regular order of business was suspended for an address by Dr. Noguchi on the work he has recently been doing on the bacteriology of trachoma. The organism which he has isolated is a Gram-negative, aerobic bacillus, possessed of motility which may last 35 days in the special medium used for culture. Blood serum from trachoma cases produces marked agglutination of the cultured bacilli, which is not the case with serum from non-trachomatous cases. All Noguchi's bacteriological and experimental results have been verified by Verhoeff in Noguchi's laboratory, while de Schweinitz and Wilmer have expressed clinical agreement with them. The original inoculations were carried out by Noguchi in New Mexico among the Indians at the request of a committee of ophthalmic surgeons, appointed by the Secretary of the Interior, consisting of Drs. E. L. Posey, P. Knapp, W. H. Wilder, and Henry H. Proctor. Dr. Posey has recently given some account [3] of the incidence of trachoma among the Navajo tribe in the South-West States, and of the important activities of the United States Government to combat it. Dr. Proctor has also long been interested in trachoma among the Indians, and it is largely due to his influence that Noguchi left his work at the Rockefeller Institute to pay a scientific visit to New Mexico.

MEDICAL SCIENCE IN THE CITY OF YORK.

THOSE members of the medical profession who attended the services held last week in celebration of the 1300th anniversary of the Consecration of York Minster must have been assured of the falseness of that saying quoted by Sir Thomas Browne, "Ubi tres medici, duo athei." The long and intimate connexion of the City of York with medicine and surgery, the vastness of the Minster, the pomp and circumstance of the processions and of the services must have left a deep feeling of religious awe on the minds of all present. The seventh day of the celebrations was especially associated with the universities, colleges, and schools. It opened with a solemn Eucharist and procession followed by a midday service. The representatives of the various bodies robed in the neighbouring Church of St. Michael-le-Belfry and entered the Minster in procession through the great west door to the places allotted to them in the nave. The service was fully choral, and a sermon was preached by the Bishop of Manchester in the presence of a very large congregation. There were no representatives from the Royal College of Physicians of London, but the Royal College of Surgeons of England sent their President, Sir Berkeley Moynihan, and two members of the Council, Sir D'Arcy Power and Sir James Berry, to bear witness to the good work which the medical profession has always done in the City of York.

ACTIVITY AND HEALTH IN INDUSTRY.

THE relation between efficient activity and healthy contentment is passing from the realm of theoretical probability into that of ascertained fact. The progress made is reported to us annually by the Industrial Fatigue Research Board, to whose work the historian of the future will, we believe, accredit no little share in the decline of industrial discontent. The latest report [4] indicates the scope of matters under investigation, which include the use of rest pauses in spells of labour, and the value of rhythm in alternating rest and activity; accident causation and the part played by the personal factor, showing how the less efficient workers suffer more sickness and sustain more accidents than good workers; study of the influence of ventilation upon health and output; and the advantages accruing from vocational guidance. Special inquiries under industrial conditions are also afoot into sickness among cotton operatives and among printers, into load carrying, telegraphist's cramp, vision and illumination; others are proceeding in the laboratory into the laws of muscular exercise and the acquisition of skill. All these inquiries, whatever their objective, have one significant characteristic. The Board is satisfied that improvement of the conditions or methods of work for the worker means *ipso facto* an increase in his output, and accordingly the introduction of such methods can never be a matter of conflict between the interests of the employer and those of the worker; these are both

[3] Jour. Amer. Med. Assoc., May 21st.

[4] Seventh Annual Report of the Industrial Fatigue Research Board to Dec. 31st, 1926. H.M. Stationery Office. 1927.

affected in the same direction. In no other country is research on these lines being carried on so broadly or systematically, and British industry is slowly learning to appreciate the economic value of the work done and to benefit thereby.

INFANT WELFARE CONFERENCE.

ABOUT 700 delegates were appointed to the National Conference on Maternity and Infant Welfare, which began its sessions on July 5th. Sir Arthur Stanley, chairman of the Central Council for Infant and Child Welfare, took the chair at the opening of the proceedings and was supported on the platform by Mr. Neville Chamberlain (Minister of Health) and Mrs. Chamberlain, Lady Chatterjee (wife of the High Commissioner for India), medical representatives of the Ministry of Health and of the Scottish and Welsh Boards of Health, and many representatives of the voluntary and statutory bodies interested. As President of the conference Mr. Chamberlain delivered an address to a crowded meeting in the Great Hall of the British Medical Association. He expressed optimism about the probable results of recent legislation and hoped that Bills would become law during the present session for the registration of nursing homes and for making better provision for mentally defectives. The circulars recently issued by the Ministry for securing better notification and treatment for puerperal fever and pyrexia and more prompt attention for ophthalmia neonatorum had met with a good response from the local authorities. With regard to the former, steps were being taken to provide the help of specialists, skilled nursing, and hospital treatment. Mr. Chamberlain went on to refer to the maternal mortality-rate from childbirth and to the need for increased effort to reduce it. He enumerated many hopeful features. Orthopædic schemes had been inaugurated by 129 maternity and child welfare authorities, often in conjunction with voluntary associations. Antenatal work, with its hope both for mothers and babies, was gradually growing. Light treatment was becoming very popular; perhaps, indeed, too popular, for the results were not yet very certain and the dangers from imprudent and promiscuous treatment not small. The supervision of a medical expert and a specially trained nurse were essential. Another gratifying feature of the situation was the increase of trained midwives and health visitors in rural districts. One of the great needs was more attention and better supervision for the child between its first year and its entrance to school. Mr. Chamberlain welcomed these conferences as a sign of the invaluable triple partnership of the Ministry, the statutory health authorities, and the voluntary bodies. Each had something special to offer. The volunteers provided enthusiasm and the backing necessary for new measures, the statutory health authorities provided trained competence and continuity of policy, and the State provided a broader outlook and a wider experience.

THE British Medical Association starts its Edinburgh meeting next week. The annual representative meeting will begin on July 15th and the scientific sections, of which the provisional programme will be found on p. 82, will meet on July 20th, 21st, and 22nd. A centenary celebration, commemorative of the birth of Lord Lister, will be held under the presidency of the Earl of Balfour on Wednesday, July 20th, at 8 P.M., in the McEwan Hall, when addresses will be given by Sir W. Watson Cheyne, Prof. Tuffier, of Paris, Prof. Harvey Cushing, of Harvard, and Dr. James Stewart, of Halifax, Nova Scotia. A Lister memorial volume, to which Sir Edward Sharpey-Schafer, Mr. Alexander Miles, and Prof. John Fraser have contributed chapters, has been prepared under the editorship of Dr. A. Logan Turner. The quarterly meeting of the Royal Medico-Psychological Association will also take place in Edinburgh in the third week of July, the discussions being held jointly with the Section of Mental Diseases of the British Medical Association.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXI.

THE TREATMENT OF MALIGNANT DISEASE OF THE UTERUS.

II. OPERATIVE METHODS AND IRRADIATION.

Wertheim's Operation.

THE operation and, with a few negligible exceptions, the *only* operation worth performing for carcinoma of the cervix, is that introduced by the Viennese gynæcologist, Wertheim, in the early years of this century. Its inventor claimed that by its means about half of the patients who survived it remained well and free of recurrence five years afterwards. Wertheim's claims were fiercely criticised, firstly, on the grounds that his operation had an excessive operative mortality, and, secondly, that his surprising after-results were too good to be true, and even to the present day the operation is looked askance upon in many quarters, and in some countries, notably the United States, it has never fairly been put on trial.

The reason for this is that the operation, if carried out properly, is a very difficult one, and a surgeon taking it up must either learn from one already expert or educate himself, the latter alternative, of course, taking a long time. In the earlier days there was no such choice; surgeons had to educate themselves, with much pain and heavy anxiety, and it is not surprising that many of them, after a few disheartening failures, abandoned the procedure. Those, however, who by one route or the other will take the trouble to acquire the necessary experience and expertness, will find that the claims of the inventor were by no means exaggerated, but just the plain truth, and dependent neither on remarkable good luck nor extraordinary operative gifts. I took up the operation in 1907, and have continued to perform it ever since, and the results I have obtained absolutely substantiate Wertheim's claims. Whilst following the main lines laid down by its inventor, I have made it rather more extensive; thus, I remove the regional glands in every case, not merely when they are obviously enlarged, and I excise practically the whole vagina instead of merely the upper half. Like Wertheim, my earlier cases show a much higher operative mortality than my later ones, 20 per cent. against 12 per cent., but, as I have repeatedly pointed out, the figure of the operative death-rate chiefly depends upon whether or no the operator chooses to undertake very advanced cases, for amongst such the operative mortality is necessarily high. In my series are included a number of "last chance" cases; in fact, I have operated on over 60 per cent. of all the patients submitted to me. Last year I investigated the outcome of 214 radical abdominal operations performed by me between April, 1907, and October, 1921, and to show what can be done for those suffering from this cruel disease I cannot do better than summarise my results here:—

Of 340 unselected patients, 214 had the radical abdominal operation performed on them and 180 survived the operation (operation mortality, 15·8 per cent.).

Five years afterwards, of the 180 recovered patients, 85 were alive and well, 82 had died of recurrence, and 13 had been lost sight of or died of other disease.

Five years' freedom from recurrence was considered by Wertheim as an "absolute cure," but it is an unfortunate fact that 10 per cent. of all recurrences take place between the fifth and tenth years, after which a patient may be regarded as free of any further risk. Taking this into consideration, surgery's achievement in the operative cure of carcinoma of

the cervix may be thus expressed: that were it possible for a surgeon to perform a series of Wertheim's operations in one day instead of spreading them over a number of years, and keep in touch with all the survivors, nor lose any of them by other disease, he would find at the end of ten years that slightly more than one-half of those who had survived the operation had died of recurrence, whilst slightly less than one-half were permanently cured.

Radium and X Rays.

The results that I have obtained by operative treatment are so far superior to anything that in this country up to the present has been attained by irradiation, that I most strongly believe that whenever a growth is removable it should be removed. My experience of radium in the treatment of carcinoma of the cervix is now of long duration, as it has been used in quantity at the Middlesex Hospital for the last 17 years. The results obtained up to the last few years were most disappointing. In some cases a remarkable local disappearance of the growth occurred, and the patient became free of bleeding and discharge for many months or even a year or more; at the end of that time, however, the symptoms recurred, and the patient steadily went downhill and died. In other cases, the spread of the growth was very definitely checked, and the bleeding and discharge much lessened, though the growth remained grossly apparent to the examining finger. Such patients had radium applied at intervals over long periods, but, in spite of it, steadily lost ground, and, what was perhaps the more distressing feature, lost hope. Their lives were undoubtedly prolonged by the treatment, but the months or years gained could scarcely be called happy ones, beset as they were with alternating hope and fear, of which fear eventually predominated. In a few exceptional cases, a cure comparable to an operative cure—namely, freedom from any sign of the growth for over five years—was attained. Against these few complete successes and many partial successes had to be set an equally large number of patients in whom the radium stimulated the growth to increased activity, and materially shortened the lives of the patients by increasing their pain, bringing on foul discharge where none existed before, or producing fistulæ in the rectum or bladder. It must, however, be pointed out that all the patients of whom I am speaking were those in whom the growth was too advanced for operative removal; except in a few instances, radium has not been used in operable cases. Equally disappointing results have been recorded by many other writers.

Of recent years, however, much better results have been published by certain workers, chiefly on the continent and in America, and claims have been made to a percentage of cures nearly equal to the best of those claimed for surgery. The better results obtained are stated to be due to an improved technique in the using of radium, and this improved technique is now being used in England at various places, Middlesex Hospital included. It is too early to speak with confidence yet of the results which have been obtained by these new methods, but judging from cases that have come under my cognisance, I think that the results are better than they used to be. The point that concerns us at present, however, is whether radium should be used in preference to or as an alternative to operation in cases in which the growth is removable, and up to the present no figures published in this country justify such a change in policy. For cases too advanced for surgery, on the other hand, radium is the treatment of election, and superior in my opinion to deep X ray therapy. Even to-day with the improved technique the results obtained in these advanced cases are very unequal. In some great improvement is manifested, whilst in others the patients are made undoubtedly worse and their lives shortened. My experience of deep X ray therapy has been an unfortunate one, for I know of no case in which the growth permanently disappeared, and only a few in which material improvement was obtained. The drawback to X rays is that each application makes the patient so ill. X rays and radium may be used in combination.

Speaking generally of the results likely to be obtained by irradiation, I think it may be said that whilst they are better than they used to be, too much can easily be hoped from them at the present time. A perusal of the literature bearing on the subject shows a discordance of claims as marked in the case of individual workers as are the results in individual patients, and leaves an unbiased observer in a puzzled frame of mind.

Treatment of Carcinoma of the Body of the Uterus.

In the case of carcinoma of the body of the uterus, the only hope of cure lies in a radical operation. It is not necessary in this disease to subject the patient to an operation as severe as Wertheim's operation, because the route of spread of corporeal cancer is different from that of cervical disease, and occurs along tracts more easily compassed by the surgeon's knife. The common path of lymphatic permeation is along the lymphatics accompanying the ovarian vessels up to the glands along the upper half of the abdominal aorta. There is no tendency until very late for the growth to invade the lymphatics accompanying the uterine arteries to the side wall of the pelvis, and therefore there is no need for that wide excision of the paravaginal and paracervical tissue which is necessary in cervical cancer. Most patients with corporeal cancer actually die of metastatic deposits due to the growth penetrating the uterine wall, and entering into the peritoneal cavity, and this often occurs long before the cancer cells have reached the aortic glands. The operation indicated is a total hysterectomy, taking with the uterus the ovaries, tubes, and upper part of the broad ligaments as far outwards along the ovario-pelvic ligaments as possible. This is not a severe procedure in most cases, and the operative mortality is not a high one (about 5 per cent.), and would be lower still if it were not that many of the patients are elderly women, enfeebled by long-continued bleeding and foul discharge. As regards the chances of permanent cure, these are at least as good as those yielded by Wertheim's operation—that is to say, that about half the patients recovering from the operation are permanently cured.

Radium and X Ray Treatment in Corporeal Cancer.

Radium is practically useless in corporeal cancer. No doubt there are certain cases where the growth is quite superficial on the endometrium, in which radium introduced into the uterus would destroy permanently all the malignant cells, but we have no means of ascertaining the depth to which the growth has spread in the uterine wall, short of removing the uterus and examining it afterwards, and hence to use radium in preference to an operation, even where the growth is apparently a very recent development, would be wholly unjustifiable. Moreover, it is in these early growths that surgery can be certainly relied upon to give a permanent cure. Deep X ray therapy I have employed and seen employed in many cases, but I have not seen one in which the patient was cured, and very few in which duration of the patient's life appeared to be lengthened by its use. Whether it should be used as a means of comforting the patient and the patient's friends with the idea that something can be done is a moot point, for the treatment makes the patient feel very ill, and unless carried out in hospital is expensive.

VICTOR BONNEY, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng.,
Surgeon to the Chelsea Hospital for Women; Assistant Gynæcological Surgeon to the Middlesex Hospital, London.

Special Articles.

THE FREEDOM RESEARCH FUND.

THE Freedom Research Fund was instituted in October, 1925, by the provision of a gift of £50,000 for the promotion of research work in connexion with the clinical laboratories of the London Hospital. Research workers were elected during the year 1926 and the following brief account indicates the lines along which research has been carried out during the first active year of the Fund. The work has been much assisted by the interest and coöperation of the honorary staff of the London Hospital and in particular by the daily intercourse which takes place between the laboratory workers and the staff of the medical unit.

Filterable Viruses.—During the year 1926–27 Dr. S. P. Bedson has been engaged on a study of the viruses of herpes, zoster, and chicken-pox with two main objects in view: (*a*) to throw light on the nature of filterable viruses in general, (*b*) to work out the inter-relationship of these three viruses with special reference to the supposed identity of the viruses of zoster and chicken-pox.

In the first of these two problems the virus of herpes has been employed and the results obtained, generally speaking, support the view that this virus is a particulate organised form of life. This work is being continued. Little advance has been made with the second and subsidiary problem owing to the failure of all efforts to transmit zoster and chicken-pox to laboratory animals. It has not, however, been abandoned. In addition, the opportunity has been taken of investigating other vesicular conditions such as dermatitis herpetiformis, hydroa gravidarum, and pemphigus.

Dr. Bedson has also investigated the rôle of the spleen in purpura. This work has been confined to an investigation of the normal mode of destruction of the platelet, and evidence has been adduced to show that this function is performed by the phagocytic cells of the spleen.

The Antigenic Properties of Serum Proteins.—Miss S. G. Robinson has commenced a study of the antigenic properties of purified serum proteins of different animal species, the object being to find out how far the antigenic behaviour of these lipoid-free proteins parallels their physical and chemical properties. At the same time she has been investigating the antigenic relationship of several Bence-Jones proteins isolated by Dr. L. F. Hewitt from cases of myelomatosis. Her work is not yet sufficiently advanced to warrant the drawing of any conclusions.

The Functional Capacity of the Lacteals.—Dr. H. W. Florey has been engaged on an investigation of the functional capacities of the lacteals of various animals. The rhythmical contractions observed in these vessels in guinea-pigs have been specially studied. In collaboration with Dr. P. Fildes, an examination has been made of the curative effects of massive intrathecal doses of antitoxin as compared with intravenous administration. The conclusion was arrived at that no advantage could be found, in rabbits, in the former method of giving antitoxin. With Dr. H. M. Marvin, observations are being made on the control of the cerebral circulation and the significance of the several factors involved.

Proteins of the Cerebro-spinal Fluid, Blood, and Urine.—Dr. Hewitt has worked out a method for the accurate determination of the total protein content and the amount of albumin and globulins in the cerebro-spinal fluid. A number of normal and pathological fluids were examined and characteristic alterations were found in certain conditions, especially in general paralysis of the insane. With Dr. Florey he is investigating the effect of various drugs on the protein content of the cerebro-spinal fluid.

Proteins of the blood, milk, eggs, &c., have been isolated by Dr. Hewitt in the pure state free from lipoids and characterised by their optical rotation and dispersion. The immunological relations of some of the proteins are receiving attention.

Albumin prepared from the urine of nephritic patients has been shown to have the same optical rotation and dispersion as serum albumin. Bence-Jones proteins from the urine of patients with myelomatosis are being investigated physico-chemically.

Osmotic Pressure.—In conjunction with Dr. J. R. Marrack the osmotic pressures of normal and nephritic sera and of isolated proteins are being measured under different conditions, in connexion with the study of the causes of œdema. The adsorption of various substances by proteins under various conditions is being studied. The occurrence of acetone bodies in the blood of diabetics is being followed (with Miss Brown).

MEDICINE AND THE LAW.

Mosquitoes as a Nuisance.

FURTHER information is now available to supplement the account given in this column on June 25th of the Scottish decision, believed to be the first of its kind, that, if a landowner leaves ditches in a stagnant condition, so that they become a breeding-ground for mosquitoes, to the annoyance of local residents, his action or neglect amounts to a nuisance within the Public Health (Scotland) Act, 1897.

The Section upon which the local authority of the county of Renfrew relied was Section 16, which contains a general definition of nuisances. The Section begins, "For the purposes of this Act," and then enumerates a list of matters which "shall be deemed to be a nuisance liable to be dealt with summarily in manner provided by this Act." The second group of items in the list consists of:—

> "Any street, pool, ditch, gutter, watercourse, sink, cistern, water-closet, earth-closet, privy, urinal, cess-pool, drain, dung-pit or ash-pit, so foul, or in such a state, or so situated, as to be a nuisance or injurious or dangerous to health."

The framework and most of the wording of the Section is founded upon the earlier provision of the English Act (Section 91 of the Public Health Act of 1875), but the English enactment is not quite so elaborate; it omits the words "street," "sink," "cistern," "water-closet," "earth-closet" and "dung-pit." The corresponding London provision (Section 2 of the 1891 Act) is as wide as the Scottish provision, except that it does not contain the words "street" and "sink." It will be noted, however, that the material words "pool, ditch, gutter, watercourse" are common to all three Acts.

The sheriff-substitute in the Paisley case found the following facts: the defender in the action was the proprietor in trust of certain lands at Muirend, Cathcart, comprising three ditches of which complaint was made; the ditches were close to a residential suburb of Glasgow; through the proprietor's neglect they had become so much encumbered with silt and vegetation that they were ineffective as water courses, and that the water which they should have conveyed had been largely thrown upon the adjacent ground; they thus became the breeding-ground of mosquitoes which, to some extent in the autumn of 1925, and to a large extent in the autumn of 1926, attacked people residing in the vicinity; the bites of the mosquitoes caused pain and swelling, and in some cases septic sores, and the presence of the mosquitoes caused reasonable apprehension and diminution of comfort in the community; finally, there was a reasonable probability of the repetition of these conditions in following years. The court proceeded to find, as a matter of law, that the ditches were watercourses in such a state and so situated as to be a nuisance, and injurious or dangerous to health within the

meaning of the statute, and that the proprietor of the land was the author of the nuisance. The latter was therefore ordered to clear the ditches and maintain them properly in future.

Numerous complaints of mosquito bites reached the public health department in Glasgow last autumn from the south-eastern side of the city where these lands are situated. The medical officer detailed to investigate the complaints found the bites to be of varying degrees of seriousness, according to the susceptibility of the patient. Some of the victims, especially elderly ladies, were confined to bed by their medical advisers. In some cases the swelling and redness which developed round the bites resulted in a blister which, when broken, became infected by septic organisms from the skin or clothing. The land on which the ditches stood was a tract of 15 acres known as Bogton Marsh. Presumably no legal consequences follow if such land is left neglected upon a moorland void of human habitation; but the spread of building outward from Glasgow evidently imposed a new obligation upon the landowner. The ground was low-lying, and, in periods of moderate flooding, the water overflowed and covered it continuously. Three types of mosquito are stated to have been found—*Anopheles bifurcatus*, *Culex pipiens*, and *Culicella morsitans;* the first and second of these bite readily both out-of-doors and indoors.

Legal Effect of Shock following Warning of Death.

The *Times* of June 21st reported a case in which an agreement was set aside on an unusual ground. The ground was that the agreement (for the sale of a partnership business) was entered into between two partners at a moment when one of the two was suffering from mental shock in consequence of his having just been told by a specialist that he was suffering from cancer of the stomach and that his death was imminent. It was not suggested that the shock made him insane, but it was contended that the shock of the warning benumbed his mind and made him incapable of bargaining in a matter of business with a man of normal health. After his death the Public Trustee (as his personal representative) applied to the Chancery Court of Lancaster to have the agreement set aside, and the court granted the application and ordered the agreement to be delivered up for cancellation. The agreement had related to the sale of the dying partner's share. The court considered that the share had not been properly valued and that the agreed price was less than the true value, the bargain being thus an improvident one from the point of view of the dying partner. The Vice-Chancellor expressed the opinion that there was a fiduciary relationship between the dying partner and the other partner who was a party to the agreement; this being so, the onus was upon the surviving partner to prove that the transaction was fair and righteous; in the opinion of the court he failed to discharge this onus. There was a conflict of evidence as to what was the effect of the specialist's warning, whether the dying man received it in a spirit of resignation or whether (as the specialist himself concluded) he was so acutely affected by shock that his judgment was overthrown. As already stated, the court took the latter view. It was proved in evidence that the dying man had always been obsessed by a fear of cancer; possibly therefore he was regarded as predisposed or particularly exposed to shock in this respect.

BIRKENHEAD JUBILEE APPEAL.—The Mayor of Birkenhead is anxious that the Jubilee of the Incorporation of the Borough should be marked by a determined effort on the part of all classes to put the leading charitable institutions in the town on a sound financial basis. The minimum sum of £20,000 is required to be divided amongst the Birkenhead General Hospital—which is celebrating its centenary next year—the Maternity Hospital, the Birkenhead and Wirral Children's Association, and the local Invalid Children's Association. Over £6000 has already been promised.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING AT EDINBURGH.

PROGRAMME OF THE SCIENTIFIC SECTIONS.

THESE sections will meet from 10 A.M. to 1 P.M. for papers and discussions on Wednesday, Thursday, and Friday, July 20th, 21st, and 22nd. Some of the sections—notably Diseases of Children, Preventive Medicine, Physiology and Biochemistry, Tropical Diseases, Forensic Medicine, Tuberculosis, and Venereal Disease—have arranged for discussions or demonstrations to take place in the afternoons also.

The following Sections will meet on three days:—

Medicine.

President: Prof. G. Lovell Gulland. Vice-Presidents: Prof. J. Hill Abram, Dr. R. A. Fleming, Dr. H. Morley Fletcher, Dr. W. T. Ritchie. Hon. Secretaries: Dr. George Graham, Dr. G. D. Mathewson.

Provisional Programme.—July 20th.—Discussion: The Results of Insulin Therapy in Diabetes Mellitus. To be opened by Prof. Hugh MacLean; followed by Dr. George Graham and Prof. D. Murray Lyon.

July 21st.—Discussion: The Treatment of Acute Lobar Pneumonia. To be opened by Prof. John Hay; followed by Dr. H. Morley Fletcher and Dr. A. Fergus Hewat.

July 22nd.—Discussion: The Pathology and Treatment of Pernicious Anæmia. To be opened by Prof. G. Lovell Gulland; followed by Dr. A. F. Hurst.

Surgery.

President: Prof. D. P. D. Wilkie. Vice-Presidents: J. W. Dowden, Mr. F. J. Steward, Mr. J. W. Struthers, Mr. H. Wade, Mr. A. M. Webber. Hon. Secretaries: Mr. J. M. Graham, Mr. E. C. Hughes.

Provisional Programme.—July 20th.—Discussion: Tuberculosis of the Kidney. To be opened by Sir John Thomson-Walker; followed by Dr. A. Rollier (Leysin), Prof. A. Fullerton, Mr. H. Wade, Mr. J. F. Dobson, and Mr. B. J. Ward.

Paper: Mr. W. Rankin: The Treatment of Acute Osteomyelitis by Primary Diaphysectomy.

July 21st.—Discussion: The Place of Surgery in the Treatment of Toxic Goitre. To be opened by Mr. T. P. Dunhill; followed by Prof. G. R. Murray, Mr. C. Thurstan Holland, Prof. R. E. Kelly, and Dr. John Eason.

Paper: Sir Almroth E. Wright: The Rational Treatment of Infected Wounds.

July 22nd.—Discussion: Chronic Appendicitis. To be opened by Mr. Wilfred Trotter; followed by Mr. J. W. Dowden, Mr. Victor Bonney, Mr. A. J. Walton, and Mr. H. J. Paterson.

Paper: Mr. A. MacLennan: Burns.

Obstetrics and Gynæcology.

President: Dr. James Haig Ferguson. Vice-Presidents: Mr. T. Watts Eden, Dr. Gibbon FitzGibbon, Dr. W. Fordyce, Prof. R. W. Johnstone, Mrs. E. Vaughan-Sawyer. Hon. Secretaries: Dr. Daniel Dougal, Dr W. F. T. Haultain.

Provisional Programme.—July 20th.—Discussion: The Relation of Pregnancy to General Diseases. To be opened by Prof. J. M. Munro Kerr (Cardiac Diseases), Dr. E. Rist, of Paris (Tuberculosis), and Prof. F. J. Browne (Venereal Diseases); followed by Dr. G. FitzGibbon and Dr. Mary H. J. MacNicol.

July 21st.—Discussion: The Hygiene of Menstruation in Adolescents. To be opened by Prof. R. W. Johnstone, Dr. J. H. P. Paton, and Mrs. A. E. Sanderson Clow; followed by Mrs. E. Vaughan-Sawyer.

July 22nd.—Papers: Dr. F. A. E. Crew: The Effect upon the Sex Ratio of Conception Early and Late in Relation to the Œstrous Cycle of the Rat. Dr. D. A. Miller: Failed Forceps Cases. Dr. D. Dougal: The Clinical Features of Ectopic Pregnancy. Dr. B. Solomons: Some Points in the Technique of the Low Segment Cæsarean Operation. Prof. W. Fletcher Shaw: Uterine Fibroids after the Menopause.

Pathology and Bacteriology.

President: Prof. J. Lorrain Smith, F.R.S. Vice-Presidents: Dr. W. R. Logan, Prof. T. J. Mackie, Dr. H. D. Wright. Hon. Secretaries: Dr. James Davidson, Dr. H. J. Parish.

Provisional Programme.—July 20th.—Discussion: Growth in its Pathological Relations. To be opened by Dr. A. Leitch; followed by Prof. R. Muir, Dr. G. W. de P. Nicholson, Prof. J. Shaw Dunn, Prof. M. J. Stewart, and Prof. E. H. Kettle.

July 21st.—(Joint meeting with Section of Comparative Medicine). Discussion: Immunity. To be opened by Dr. R. A. O'Brien and Prof. C. H. Browning; followed by

Prof. R. Muir, Dr. H. D. Wright, Colonel W. F. Harvey, and Prof. T. J. Mackie.

July 22nd.—(Joint meeting with Section of Comparative Medicine). Discussion: Aspects and Problems of Comparative Medicine. To be opened by Prof. Basil Buxton; followed by Major G. W. Dunkin, Mr. W. H. Andrews, Dr. F. A. E. Crew, Dr. H. H. Scott, Prof. R. T. Leiper, Mr. J. W. Brittlebank, Mr. A. Goften, Mr. T. W. M. Cameron, and Mr. J. McAllan.

Therapeutics and Pharmacology.

President: Prof. J. A. Gunn. Vice-Presidents: Prof. A. J. Clark, Prof. F. R. Fraser, Dr. E. P. Poulton. Hon. Secretaries: Dr. E. G. Holmes, Dr. C. G. Lambie.

Provisional Programme.—July 20th.—10 A.M., Discussion: Clinical Methods of Administration and Therapeutic Uses of Oxygen. To be opened by Dr. E. P. Poulton; followed by Dr. H. Whitridge Davies and Dr. W. T. Ritchie. 12 noon, Paper: Prof. J. A. Gunn: Expectorants.

July 21st.—Discussion: The Therapeutic Uses of Calcium Salts. To be opened by Prof. F. R. Fraser; followed by Dr. L. G. Parsons Mr. C. P. Stewart (Biochemical Aspect), Dr. G. H. Percival (Pharmacological and Therapeutic Aspect), Prof. L. Blum (Strasbourg), Dr. G. C. Linder (Tetany), and Dr. N. F. C. Burgess.

July 22nd.—Discussion: The Action and Uses of Ovarian Extracts. To be opened by Prof. W. E. Dixon; followed by Dr. K. A. Coward (Standardisation), Mr. A. S. Parkes (Physiological), Dr. W. R. Addis (Clinical), and Prof. J. M. Munro Kerr (Gynæcological).

Diseases of Children.

President: Prof. John Fraser. Vice-Presidents: Dr. H. C. Cameron, Dr. A. D. Fordyce, Dr. Charles McNeil. Hon. Secs: Dr. Helen M. M. Mackay, Dr. Lewis Thatcher.

Provisional Programme.—July 20th.—Discussion: Acute Pneumonia in Early Childhood. To be opened by Dr. Charles McNeil and Dr. Agnes R. Macgregor conjointly; followed by Prof. Leonard Findlay, Dr. J. H. Thursfield, Colonel W. Glen Liston, and Dr. N. S. Carmichael. Afternoon, Demonstration: Dr. W. A. Alexander: Acute Pulmonary Conditions in Childhood, illustrated by specimens, X ray prints, large sections, and microscopic preparations Surgical demonstration at Royal Edinburgh Hospital for Sick Children.

July 21st.—Discussion: Acute Intestinal Obstruction in Infancy and Childhood. To be opened by Mr. Alex. MacLennan; followed by Mr. L. E. Barrington-Ward, Miss G. M. A. Herzfeld, Mr. F. C. Pybus, and Mr. Norman M. Dott. Afternoon, Demonstration of Medical Cases at Royal Edinburgh Hospital for Sick Children.

July 22nd.—Discussion: Therapeutic Modification of the Diet in Infancy: What can be Achieved by it? To be opened by Dr. H. C. Cameron; followed by Dr. A. D. Fordyce, Dr. G. B. Fleming, and Dr. Lewis Thatcher.

Mental Diseases.

President: Prof. G. M. Robertson. Vice-Presidents: Dr. Bernard Hart, Dr. John Keay, Colonel J. R. Lord, Dr. H. C. Marr. Hon. Secretaries: Dr. R. D. Gillespie, Dr. W. M. McAlister.

Provisional Programme.—July 20th.—Discussion: Chronic Sepsis as a Cause of Mental Disorder. To be opened by Dr. William Hunter; followed by Sir Berkeley Moynihan, Dr. D. Chalmers Watson, Dr. E. Goodall, Dr. C. H. Bond, and Dr. W. F. Menzies.

July 21st.—(Joint meeting with the Section of Neurology.) Discussion: Epidemic Encephalitis. To be opened by Dr. Ivy Mackenzie (Epidemiological Considerations), Dr. J. G. Greenfield (Pathology), Dr. R. M. Marshall (Mental Aspects), and Dr. G. Riddoch (Chronic Encephalitis); followed by Dr. E. Mapother, Dr. H. Devine, Dr. W. J. Adie, and Dr. W. A. Potts.

July 22nd.—Discussion: Points in the Lunacy Commission (England) Report—(*a*) Are the existing safeguards against wrongful detention adequate? (*b*) How far is judicial intervention necessary in the process of certification? (*c*) What additional facilities are required for early treatment? To be opened by Prof. G. M. Robertson.

The following Sections will meet on two days:—

Neurology.

President: Prof. Edwin Bramwell. Vice-Presidents: Dr. A. Ninian Bruce, Dr. J. G. Greenfield, Dr. F. M. R. Walshe. Hon. Secretaries: Dr. E. A. Carmichael, Mr. N. M. Dott.

Provisional Programme.—July 20th.—Discussion: The Tics and Allied Conditions. To be opened by Dr. S. A. Kinnier Wilson; followed by Prof. Guillain (Paris), Dr. A. F. Hurst, Dr. A. Stanley Barnes, Dr. T. Grainger Stewart, Dr. D. E. Core, Dr. R. G. Gordon, and Dr. W. J. Adie.

July 21st.—Joint meeting with Section of Mental Diseases. (See above.)

Ophthalmology.

President: Mr. A. H. H. Sinclair. Vice-Presidents: Mr. Wilfred Allport, Sir Arnold Lawson, Mr. H. M. Traquair. Hon. Secretaries: Mr. R. E. Bickerton, Mr. E. H. Cameron.

Provisional Programme.—July 20th.—Discussion: Optic Neuritis. To be opened by Dr. J. V. Paterson; followed by Dr. Henning Rönne (Copenhagen) and Dr. A. J. Ballantyne.

July 21st.—Papers: Miss I. C. Mann: Some Aspects of the Comparative Development of the Retina. Sir W. T. Lister: Some Points in Connexion with Detachment of the Retina. Mr. W. Clark Souter: Spontaneous Reattachment of Detached Retina. Sir Arnold Lawson: Value of Antiseptics in Modern Ophthalmic Surgery. Mr. F. Holt Diggle: Relationship between Lacrymal Obstruction and Nasal Disease. Mr. H. M. Traquair: Incidence of Tobacco Amblyopia in Edinburgh and District. Mr. A. H. H. Sinclair: Remarks on Intracapsular Extraction of Cataract, and Demonstration.

Laryngology and Otology.

President: Mr. A. Logan Turner. Vice-Presidents: Mr. J. S. Fraser, Mr. W. M. Mollison, Dr. Donald R. Paterson. Hon. Secretaries: Mr. A. R. Dingley, Mr. W. T. Gardiner.

Provisional Programme.—July 20th.—Discussion: Neurological and Mechanical Factors underlying Immobility of the Vocal Cords; their Diagnosis, Prognosis, and Principles of Treatment. It will be opened by Dr. A. Brown Kelly (Neurological Aspect) and Mr. Herbert Tilley (Mechanical Side).

July 21st.—Discussion: Otosclerosis. To be opened by Mr. G. J. Jenkins; followed by Prof. F. R. Nager (Zurich) and Dr. A. A. Gray.

Papers: Mr. Norman Patterson: Some Diseases Affecting the Thyro-glossal Tract. Dr. Stephen Young: Radiography in Mastoid Disease.

Preventive Medicine.

President: Prof. P. S. Lelean. Vice-Presidents: Dr. G. F. Buchan, Miss Harriette Chick, Dr. A. M. Hewat, Dr. G. R. Leighton. Hon. Secretaries: Dr. W. T. Benson, Dr. C. W. Hutt.

Provisional Programme.—July 20th.—Discussion: Should all Public Health Administration—Municipal, School, Factory, &c.—be Concentrated under a Single Department, and the Immediate Control in Each Executive Area be Vested in a Single Individual? To be opened by Dr. A. S. M. MacGregor; followed by Dr. F. E. Wynne, Dr. J. H. Meikle, Prof. E. L. Collis, and Dr. E. W. Hope.

July 21st.—10 A.M., Discussion: What Duties has the State in Relation to the Nation's Food-supply regarding Research, Instruction of Parents, Maintenance of Supplies, and Cooking Facilities? To be opened by Prof. E. Mellanby, followed by Dr. Eustace Hill, Dr. J. P. Kinloch, and Mr. G. Benzie. 12 noon, Paper: Pulmonary Asbestosis, by Dr. W. E. Cooke, Sir Thomas Oliver, and Prof. Stuart McDonald.

Physiology and Biochemistry.

President: Prof. Sir Edward Sharpey-Schafer, F.R.S. Vice-Presidents: Prof. P. T. Herring, Prof. D. Murray Lyon, Prof. John Mellanby, Prof. T. H. Milroy, Prof. John Tait (Montreal). Hon. Secretaries: Prof. B. A. McSwiney, Miss Laurie Walker.

Provisional Programme.—July 21st.—Morning session. Discussion: The Structure and Function of the Spleen. To be opened by Prof. John Tait; followed by Prof. J. Barcroft, F.R.S., and others. Papers: Prof. P. T. Herring: The Pineal Gland. Prof. D. Murray Lyon and Mr. W. Robson: Cystinuria. Dr. J. Crighton Bramwell: Form of the Pulse Wave. Prof. J. A. MacWilliam and Prof. G. Spencer Melvin: Optimal Rhythm in the Mammalian Heart and the Action of the Cardiac Nerves. Dr. C. Reid: The Mechanism of Voluntary Muscular Fatigue. Prof. H. E. Roaf: The Quantitative Measurement of Defects in Colour Vision. Prof. B. A. McSwiney: Structure and Movements of the Cardia. Afternoon session. Discussion: The Influence of Internal Secretions on Sex Characters. To be opened by Dr. F. A. E. Crew; followed by Mr. A. S. Parkes, Prof. E. E. Glynn, and others.

July 22nd.—Morning session. Discussion: Chemical Changes accompanying Muscular Activity. To be opened by Prof. T. H. Milroy; followed by Sir F. Gowland Hopkins, Prof. O. Meyerhof (Berlin), and Prof. G. Embden (Frankfürt). Papers: Prof. J. Mellanby: Bile as the Alimentary Stimulus for Pancreatic Secretion. Prof. J. Tait: Natural Arrest of Hæmorrhage from a Wound (illustrated with lantern slides). Dr. H. Whitridge Davies and Prof. B. A. McSwiney: Circulation Rate. Prof. R. J. S. McDowall: Physiological Considerations in High Blood Pressure. Dr. C. R. Harington: The Constitution of Thyroxin.

Afternoon session. Discussion: Hæmolysis. To be opened by Dr. E. H. Ponder; followed by Prof. J. Mellanby, Dr. R. Brinkman (Groningen), and others.

Comparative Medicine.

President: Principal O. Charnock Bradley. Vice-Presidents: Prof. J. B. Buxton, Dr. F. A. E. Crew, Major G. W. Dunkin. Hon. Secretaries: Mr. T. W. M. Cameron, Mr. J. Russell Grieg.

Provisional Programme.—July 21st and 22nd.—Joint meeting with Section of Pathology and Bacteriology. (See above.)

The following Sections will meet on one day:—

Dermatology.

President: Dr. R. Cranston Low. Vice-Presidents: Dr. W. Herbert Brown, Dr. H. D. Haldin-Davis. Hon. Secretaries: Dr. Robert Aitken, Dr. F. D. Howitt.

Provisional Programme.—July 21st.—Discussion: The Uses and Limitations of Ultra-Violet Radiations in Dermatology. To be opened by Dr. S. E. Dore.

Papers: Dr. H. C. G. Semon: The Value of Krysolgan in Lupus Erythematosus. Dr. G. B. Dowling: The Treatment of Tinea Capitis with Thallium Acetate.

Tropical Diseases.

President: Dr. Andrew Balfour. Vice-Presidents: Lieut.-Colonel E. D. W. Greig, Lieut.-Colonel W. F. Harvey, Lieut.-Colonel W. Glen Liston, Lieut.-Colonel W. P. MacArthur. Hon. Secretaries: Dr. A. R. D. Adams, Dr. J. F. C. Haslam.

Provisional Programme.—July 20th.—10 A.M. Discussions: (1) Amœbic Dysentery. To be opened by Prof. Warrington Yorke; followed by Dr. P. H. Manson-Bahr (Treatment and Epidiascopic Illustrations of Sigmoidoscope Appearances), Dr. J. Gordon Thomson, and Dr. N. Swellengrebel (Amsterdam). 11 A.M. (2) Some Problems of Malaria Prophylaxis. To be opened by Lieut.-Colonel S. P. James; followed by Sir William Prout, Lieut.-Colonel E. D. W. Greig, Dr. L. W. Hackett (Rome), and Dr. N. Swellengrebel.

Forensic Medicine.

President: Prof. H. Harvey Littlejohn. Vice-Presidents: Earl Russell, Sir Walter Schroder, Prof. Sydney A. Smith (Cairo). Hon. Secretaries: Dr. D. J. A. Kerr, Prof. J. E. W. McFall.

Provisional Programme.—July 21st.—Discussions: (1) Alcohol and the Motorist. To be opened by Dr. G. Carter. (2) The Teaching of Forensic Medicine. To be opened by Prof. J. Glaister.

Tuberculosis.

President: Dr. S. Vere Pearson. Vice-Presidents: Dr. William Brand, Dr. A. de W. Snowden, Dr. Ernest Watt. Hon. Secretaries: Dr. J. C. Simpson, Dr. R. R. Trail.

Provisional Programme.—July 22nd.—10 A.M. Discussions: (1) Radiology and Diagnosis of Intrathoracic Tuberculosis from the Point of View of Specialist and Practitioner. To be opened by Mr. H. Morriston Davies; followed by Dr. E. Rist (Paris), Dr. J. Logan Stewart, and Dr. J. M. Woodburn Morison. (2) Pathology of the Tuberculosis of Childhood and its Bearing on Clinical Work. To be opened by Prof. Eugene L. Opie (Washington University); followed by Dr. R. G. Canti and Dr. P. F. Armand-Delille (Paris). (3) Interrelation of Physician and Surgeon in Regard to Non-pulmonary Tuberculosis. To be opened by Dr. D. A. Powell and Prof. John Fraser; followed by Dr. G. H. Girdlestone.

Venereal Diseases.

President: Mr. David Lees. Vice-Presidents: Dr. Archibald Cambell, Mrs. Margaret Rorke, Mr. R. Stopford. Hon. Secretaries: Dr. F. C. Doble, Miss M. Forbes Liston.

Provisional Programme.—July 22nd.—Morning session. Discussion: The Value of Routine Examination of the Cerebro-spinal Fluid with regard to (*a*) More Accurate Knowledge, (*b*) Prognosis, (*c*) Treatment. To be opened by Mr. C. H. Mills. Clinical cases illustrating types of neurosyphilis will also be shown. Afternoon session. Discussions: (1) The Employment of Certain Constituents of the Gonococcus in Treatment and of other Constituents in Tests of Cure. To be opened by Major E. C. Lambkin. (2) The Place of Bismuth in the Treatment of Syphilis, by Mr. David Lees.

Radiology.

President: Dr. J. M. Woodburn Morison. Vice-Presidents: Mr. M. R. J. Hayes, Dr. R. E. Roberts. Hon. Secretaries: Dr. W. Crichton Fothergill, Dr. John Muir.

Provisional Programme.—July 20th.—Discussions: (1) 10 A.M. X Rays in the Diagnosis of Intrathoracic Growth. To be opened by Dr. Stanley Melville; followed by Mr. C. Thurstan Holland, Dr. A. Fergus Hewat, and Dr. D. Campbell Suttie. (2) 11.30 A.M. X Rays and Radium in the Treatment of Carcinoma of the Breast. To be opened by Dr. N. S. Finzi; followed by Dr. J. H. D. Webster, Dr. A. E. Barclay, Mr. M. R. J. Hayes, and Dr. R. Knox.

History of Medicine.

President: Dr. John D. Comrie. Vice-Presidents: Dr. Arnold Chaplin, Dr. Charles Singer, Dr. R. W. Innes Smith, Mr. Henry S. Wellcome. Hon. Secretaries: Dr. W. J. Dilling, Dr. A. Cairns White.

Provisional Programme.—July 22nd.—10 A.M. Discussion: The Historic Evolution of Disease. To be opened by Sir Humphry Rolleston; followed by Prof. G. Elliot Smith (Ancient Prototypes of Modern Disease), Dr. G. M. Cullen (World Epidemics and their Relationship in Cause and Effect to Social Conditions), and Miss M. C. Buer (The Effect of Early Industrialism upon the Health of the Community).

Papers: 12.15 P.M. Prof. A. J. Clark: The Historical Aspect of Quackery. 12.30 P.M. Prof. W. J. Dilling: The Methods of Introduction of Drugs.

Medical Sociology.

President: Dr. F. N. Kay Menzies. Vice-Presidents: Dr. L. D. Cruickshank, Sir Henry S. Keith, Lord Mackenzie, Sir Arthur Stanley, Sir Norman Walker. Hon. Secretaries: Dr. T. Yule Finlay, Mr. B. S. Simmonds.

Provisional Programme.—July 22nd.—Discussion: The Future Relationship of Municipalities to the Voluntary Hospitals of this Country. To be opened by Mr. H. L. Eason and Mr. M. A. Reynard; followed by Sir Henry Keith, Sir Arthur Stanley, and others.

THE PRACTICE OF DENTISTRY IN THE IRISH FREE STATE.

(FROM OUR DUBLIN CORRESPONDENT.)

THE Minister for Industry and Commerce has introduced to the new Dail the same Bill to provide for the registration of dentists as was introduced to the last Dail in May, though it was not then proceeded with. It is likely that the several stages of the Bill will be taken rapidly, as the Government hopes for an early adjournment of the Oireachtas. The Bill is framed in order to validate an agreement between the Governments of Great Britain, of the Irish Free State, and of Northern Ireland. It provides for the establishment of a Dental Board which is to control a Register of Dentists. All persons at present on the General Dentists' Register and all persons who in the future are in possession of a degree or licence in dental surgery, granted by a university or college in the Irish Free State having power to grant the same, are entitled to be registered. The Board is empowered to investigate complaints of infamous or disgraceful conduct in a professional respect, and if in its opinion the complaints are justified, to send a report to the Medical Council. The Medical Council, on consideration of such report and after giving an opportunity of being heard to the person affected, may direct the Board to erase the name of such person from the Register. All such decisions are subject to appeal to the High Court. The supervision of education is entrusted, not to the Dental Board, but to the Medical Council. The scheme as a whole seems to be satisfactory, but two sections call for criticism. In Section 3 (3), dealing with the constitution of the Dental Board, it is provided that one member is to be elected by persons registered under Section 3 of the Dentists Act, 1921, while four are to be elected by those who are registered otherwise than under that section. It is a matter of question whether it is wise to perpetuate this grouping of the members of the dental profession. But it is clear that, if this separate representation is to be set up, it should be for a time only. The persons registered under Section 3 of the Act of 1921 are a vanishing quantity, but, as the Bill stands, as long as any of them remain they will be entitled to separate representation on the Dental Board. A period of 10 or 15 years would be adequate for this special provision, if indeed the provision is necessary at all. The other point for criticism is more important to the medical profession. Section 41 proposes to render it a punishable offence for any person, who is not registered, to practise dentistry. This is subject

to the following qualifications as regards medical men :—

Subsection (2). The provisions of the foregoing subsection shall not operate to prohibit—

(*a*) the practice of dentistry or dental surgery by a registered medical practitioner who is at the date of the passing of this Act a registered medical practitioner, or

(*b*) the performance of any surgical operation in connexion with the tissues of the mouth or jaws, or the giving of any dental treatment, advice or attendance in urgent dental cases by any registered medical practitioner.

It will be seen that the Bill proposes, in effect, to make dentistry in future a separate profession instead of regarding it, as hitherto, as a branch of surgery. It may be assumed that the universities and medical corporations will make representations to prevent the limitation proposed to be put to the functions of the medical profession. As the section stands, it appears that it depends on the interpretation of the significance of a comma whether in the future a surgeon may operate on the mouth or not, except in case of urgency.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Certified Milk.

THE report of the Scottish Board of Health, noticed in your columns last week, shows in detail the progress of the movement towards the popularisation of a higher grade milk. The response to official initiative in this campaign was at first given only by a few enthusiastic pioneers in production. Now the commercial demand is stiffening everywhere, and is demonstrated in the efforts of certain tradesmen to get the "Grade A" price for a lower grade article. The production of higher grade milk is going through the usual phases: from not needed, not wanted, not practicable, not a "paying proposition," to wanted, practicable, and paying. It is now a common experience of the child welfare centres to find even the less well-off mothers inquiring as to Certified and Grade A milk for their babies, who must have the best. The producers are now active on a large scale. At a crowded meeting of producers of Certified milk and Grade A (tuberculin-tested) milk, held in Glasgow recently, it was decided to form a society to promote the sale of such milk in Scotland. The society will be called Scottish Certified and Grade A (T.T.) Milk Producers, Ltd., and a whole-time secretary will be appointed. The expense of purveying these higher grades of milk is still out of all proportion to the small demand, and the object of the new society is to stimulate and create a better market. In some cases, where herds had been cleared of tubercle, milk of the highest grades had to be converted into cheese or fed to calves and pigs. This is not creditable to our social sense. But the omens are favourable. Paisley Corporation has contracted for Certified milk for their hospitals. Glasgow Corporation has contracted for Grade A (T.T.) milk, and it is said that the Edinburgh hospitals and infirmaries are moving in the same direction. When the pressure of the new Dairies Act begins to be felt, the whole movement will show a substantial acceleration.

The Royal Edinburgh Hospital for Sick Children.

The annual report shows that this hospital is maintaining its place worthily among the first-class Scottish hospitals. Indoor cases treated in 1926 were: medical, 1593; surgical, 1248; against 1642 and 1213 in 1925. The average residence was 17 days, and 1106 operations were performed. Other figures given are: out-patients (new), medical, 2361, with 6479 re-attendances; surgical, 3263, with 13,452 re-attendances; vaccinations, 49; total, 25,604, against 25,958 in 1925. Artificial sunlight is in active use, and is available for out- as well as for in-patients. The report says: "The benefit in selected cases is unquestionable, and there was no difficulty in getting parents to bring their children regularly for the considerable number of exposures that were necessary." The tuberculosis cases admitted to the wards "showed no decrease from the average for the years immediately preceding the war. The total of 276 included 97 cases of tuberculosis of cervical glands, 83 of abdominal tuberculosis, and 63 of tuberculosis of bones and joints." It is stated to be now generally recognised "that a very considerable proportion of cases of tuberculosis in children is due to the drinking of infected milk." The work of Stiles, Fraser, and Mitchell in this field is classical. It is disappointing to find that the cases are still so numerous, after some 20 years and more of keen effort. It is, however, to be remembered that the tuberculosis cases do not all hail from the city of Edinburgh. Of rheumatism there were 76 cases, and it is pointed out that the institutional treatment in Scotland is insufficient. The hospital is making a strong appeal for funds, which in view of the good work being done should meet with a generous response.

The Royal (Dick) Veterinary College.

Speaking at the annual prize distribution of the Royal (Dick) Veterinary College Dr. T. G. Nasmyth put in a plea for coöperation between veterinary and medical practitioner. Each would be able to tell or suggest something of interest and utility in the domain of comparative pathology. Principal O. Charnock Bradley expressed optimism as to the prospects of the veterinary profession, pointing out that appointments both at home and abroad were getting more plentiful. Lord Provost Stevenson showed how intimate the corporation and the college had always been, and how closely the work of veterinary surgeons bore on the public health. In its recently established meat regulations and its dairy regulations the Scottish Board of Health has done a great deal to make the veterinary surgeon an effective officer in the control of the meat and milk trade. The Empire Marketing Board, in the development of its scientific policy, is opening up new fields for the highest quality of veterinary men. The fact that the Highland and Agricultural Society holds its show this year in Edinburgh is of interest to those connected with the College. The society presents each year 11 silver medals to the College, and, at the very foundation of the College, gave material assistance to the founder, who would hardly recognise his modest beginnings in the large and highly equipped College of to-day.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

Artificial Pneumothorax in Childhood.

SINCE 1922 Prof. Armand-Delille, of Paris, has produced artificial pneumothorax in more than 300 young children suffering from pulmonary tuberculosis. At first he confined the treatment to one side only, but of late he has tried simultaneous bilateral pneumothorax in several cases. He claims a large number of cures and concludes that artificial pneumothorax is at present the only means at our command of arresting the course of a disease which almost always proves fatal once ulcerative lesions have developed.

Osiris Prize to Dr. Charles Nicolle.

The special committee of the Institut de France, charged with the award of the Osiris prize (100,000 francs) has announced its intention to propose the name of Dr. Charles Nicolle for acceptance at the meeting of the five constituent Academies of the Institut, which will he held this month. Dr. Nicolle, who directs the Pasteur Institute at Tunis, will thus be rewarded for the work on typhus and recurrent fevers which led to effective control of these diseases during the late war.

Small-pox in Paris.

During the last few months several hundred cases of small-pox, arising it is believed from infection

imported from Northern Africa, have appeared in Paris, 214 cases having been treated at the Claude Bernard hospital alone. Twice as many women as men have taken the infection: the case mortality has averaged 33 per cent., being higher in young children. Compulsory vaccination of everyone leaving North Africa for France is being urged.

Results obtained with a new autolysate for the treatment of cancer, devised by J. Thomas, have been presented to the Académie des Sciences. In three cases, now dating from two, three, and 12 years respectively, the autolysate has appeared to possess curative value.

The memory of Pravaz, deviser of the hypodermic syringe which bears his name on the continent, is being honoured by the erection of a monument in the town of Pont-de-Beauvoisin, in Savoy, and by giving his name to a street in Lyons.

A course in broncho-œsophagoscopy is to be held at the Lariboisière Hospital and elsewhere in Paris from July 11th to 30th, by Prof. Chevalier Jackson with the coöperation of Prof. Sébileau. It will include practical work for six applicants only, and particulars may be had from the Doyen of the Faculty of Medicine, 12, rue de l'École de Médecine, Paris.

The Director of the Hôpital Maritime de Berck-Plage (Pas-de-Calais) announces that a course in surgical tuberculosis and the elements of practical orthopædics will be given there from July 18th to 30th. Dr. Delahaye of the Hôpital will send the programme on application.

The twentieth Voyage d'Études Médicales will be held from Sept. 1st to 10th, under the scientific direction of Prof. Paul Carnot, when the spas of the Eastern Pyrenees will be visited. The inclusive fee will be 1150 francs for British participants. Particulars may be had from Mr. René Gayet, 54, rue du Faubourg St. Honoré, Paris, or in London, Mme. Juppé-Blaise, Federation of the Health Resorts of France, 19A, Tavistock-square, W.C. 1.

CHINA.

(FROM OUR OWN CORRESPONDENT.)

Prostitution in Canton.

EFFORTS are being made by the Canton Government to make legalised prostitution a thing of the past. The Governor of Kwangsi Province has promulgated an order dividing the women of the underworld into three classes. The mistresses of first- and second-class houses will be paid $60 and $30 per girl respectively as compensation for the loss they will sustain in closing their houses. A Government home has been provided for the unfortunate women who will be confined there until such time as they may enter into marriage contracts, when they will be released. This home is on similar lines to one in Chinatown, San Francisco, California, where the Federal authorities send most of the Chinese girls who are found earning their livelihood as prostitutes.

Opium Smoking.

Prominent citizens of Canton are endeavouring to get the Governor to take an interest in the suppression of opium smoking. By far the greater part of this narcotic consumed in the city comes from the province of Kwangsi, of which Canton is the capital; imported opium is much higher in price than the native-grown product. Every day 10,000 ounces of opium are sold in Canton and it is estimated that one out of every ten adult males in Canton is a smoker to a greater or lesser extent. There does not seem, however, to be the slightest chance of General S. H. Wong, the Governor, being induced even to curtail the opium traffic at this time, as the principal source of Government's income in Kwangsi is derived therefrom. Were this revenue lost it would be impossible to support the army, and in these times of civil warfare military needs come first, even at the cost of the people's welfare.

Correspondence.

"Audi alteram partem."

THE CERTIFICATION OF LUNACY.

To the Editor of THE LANCET.

SIR,—The position of the practitioner called upon to give a certificate of unsoundness of mind has become more difficult than ever. The usual procedure for bringing a patient under care and treatment has been, in private practice, by "Reception Order on Petition," that is by an Order of a judicial authority made on the petition of the relatives of the patient, the practitioner giving a certificate on the understanding that if he acts in good faith and with reasonable care he will not be liable to civil or criminal proceedings. It has now unhappily become impossible for him to have any assurance that good faith and reasonable care will secure him from legal proceedings and an adverse verdict. In any given case, even though the practitioner's good faith and reasonable care are admitted, if the jury is of opinion that a person at the time of certification was not in such a state of mental or nervous disorder as to require detention in a mental hospital, the practitioner is liable to a verdict against him, to damages and costs. In short, the jury is vested with diagnostic powers.

But beyond that emerges the curious conclusion that a doctor owes to his patient the duty of reasonable care, but that nothing short of a jury can ultimately determine whether he should take precautions to advise that the patient should be placed under care and treatment or be left without proper care and treatment. Beyond the diagnostic power conferred, the jury becomes also vested with therapeutic skill.

The practitioner must also realise that though the jury has become invested with so many of the fruits of prolonged medical education and hard-won experience, the judicial authority in the case of "Reception Orders on Petition" has virtually lost the legal powers which are nominally his. The Order which he makes is in no real sense an order at all, but is a piece of perfunctory and superfluous pantomime. It is the unhappy practitioner, who is neither legal nor judicial, who in fact is the person to make the order; at any rate the entire responsibility is his. He has to take the consequences while the judicial authority stands aside.

What then is to be done? Until further judicial decision or legislation, necessarily a long time hence, the practitioner must continue to take most serious risks, his action being ultimately determined by his sense of duty to his patients and to the public. The path of "Reception Orders on Petition," as laid down in the Lunacy Act, 1890, Sec. 4 et seq. is a most dangerous one for him. There are, however, other modes of procedure available. There is that by Inquisition, a very distinctly judicial proceeding, in which it is to be hoped that the medical witness receives the protection accorded to any other witness in a court of law. Inquisition is, however, slow, cumbersome, and expensive. There are also procedures by Summary Reception Orders, in which, as it would appear to a non-legal reader of the Act, the onus of causing an alleged lunatic to be visited by medical practitioners is divided between constables, relieving officers, overseers, and justices being judicial authorities under the Act (Sec. 13 (1) (2)). Proceedings under these Sections do not remove the dangers attending certification, but on the face of the Act it would appear to distribute responsibility more equally, and more directly to implicate the judicial authority. I venture to suggest the more extended use of summary Reception Orders, and at least think it would be desirable that the method, as applied to those cases in which proceedings by Reception Order on Petition have in the past been usual, should be ventilated and criticised.—I am, Sir, yours faithfully,

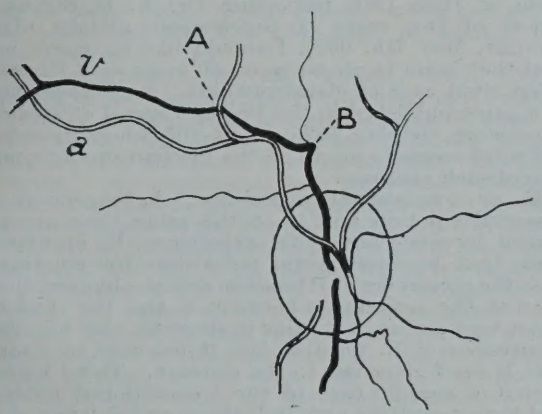
Harley-street, W., July 5th, E. D. MACNAMARA.

"RETINAL PETECHIASIS."

To the Editor of THE LANCET.

SIR,—Dr. Moreland McCrea's claim, under the above heading in your issue of June 18th, to have discovered a form of retinal hæmorrhage "not hitherto recognised," cannot be allowed as an entity. The condition is fully recognised and is generally due to venous thrombosis, of which the drawings he gives are a marked example. His further statement, that a number of patients are condemned to blindness as a "result of this incorrect diagnosis," also requires considerable qualification. Partial thrombosis tends to recovery, and the septic origin of thrombosis is also fully recognised by many of us.

If Dr. McCrea's drawings be examined, it will be seen that the obstruction to the superior retinal vein has occurred at the two points indicated in my diagram. In his drawing No. 1 the vein is blocked at A by the transverse artery crossing it, and also at B, where the vein is kinked on itself. Between A and B the vein can hardly be traced. In No. 2 the block has yielded at B though still compressed at A. In No. 3 the vein seen at A is still compressed by the artery, diminished in size, and distorted from its course—a condition well known as liable to cause



thrombosis—and a recurrence may be expected. The "petechiasis" is the result of the blocking of the vein. Where the thrombosis is mild or partial and limited to a branch of the retinal vein, it gives rise to "petechiasis" and tends to recover spontaneously, or as the result of treatment. Where it is complete, or affects the central vein, it gives rise to gross changes and large hæmorrhages, and recovery is doubtful with or without treatment.

My criticism of Dr. McCrea's case in no way detracts from the value of his paper in insisting on the septic origin of thrombosis as a cause of "retinal petechiasis." The more common cause of partial venous thrombosis is taken to be arterio-sclerosis, which again may be septic or toxic in origin. With this is associated an anatomical factor. Thrombosis takes place where the vein is crossed by an artery. In Dr. McCrea's case the branch is abnormally large and has compressed and displaced the vein, hence the thrombosis. It is a curious fact that the right superior temporal vein is the vessel most commonly affected by thrombosis, of which it will be noted Dr. McCrea's case is another example. It is the thickening and hardening of the arterial wall in arterio-sclerosis that causes the obstruction to the venous circulation when it crosses the vein.

A number of drawings illustrating the condition are on view at Hamblin's Ophthalmic Drawing Department, 15, Wigmore-street, W. 1.

I am, Sir, yours faithfully,

RAYNER D. BATTEN.

Harley-street, W., June 28th, 1927.

DIPHTHERIA IN LONDON.

To the Editor of THE LANCET.

SIR,—In reference to Mr. Maben's letter, appearing in your last week's issue, it should be noted that his figures for diphtheria incidence and mortality for eight large towns deal only with a period of 15 *months* ending March, 1927, whereas the statement in my report,* which Mr. Maben should consult, and which emphasises London as showing the highest incidence and almost the highest mortality among other large towns in Great Britain and capitals in Europe, if not the world, is based on the averages of 15 *years* ending 1925 for the towns in Great Britain, the latest date for which figures were available at the time the report was drawn up. In the tables given on pp. 21 and 22 of the report it will be seen that, among the 13 large cities, London heads the attack rates with 289 per 100,000, Portsmouth coming next with 275, and Newcastle lowest with only 96. In the death-rates, Portsmouth heads the list with 18·1, London fourth with 16·8, and Sheffield lowest with only 5·8 per 100,000.

As regards continental towns, Mr. Maben quotes only a single quarter up to March, 1927. In the report on p. 8 is given a list of the diphtheria death-rates for 1924 in 22 European capitals, headed by Edinburgh with 168, London coming third with 123, and Bucharest last with only 12 per 100,000. The statement in the report's conclusion therefore stands without modification. As regards the year 1926, for which figures in Great Britain are now available, London occupied second place on the list with an attack rate of 296, Portsmouth coming first with 404, Birmingham third, 242, Glasgow fourth, 235, West Ham fifth, 219, Sheffield sixth, 202, Edinburgh seventh, 179, and Newcastle lowest with only 72. In the mortality list London's position, seventh, with 11·9 per 100,000, is lower than in the previous 15 years' average when fourth with 16·8, but with the exception of Portsmouth heading the list with the high death-rate of 28·3, Manchester, Glasgow, and Birmingham second, third, and fourth with 13·4, 12·7, and 12·4, as against 10·5, 12·9, and 10·8, respectively, the rest of the towns show lower death-rates, notably Edinburgh and Bristol, with falls from 17·4 to 10·1, and Bristol 17·0 to 11·1. The Registrar-General's returns of diphtheria death-rates per 1000 population for 1926 are as follows :—

England and Wales ..	0·08	158 smaller towns (population 20,000–50,000)	0·06
105 County Boroughs and Great Towns, including London ..	0·10	LONDON	0·12

Again, therefore, there is reason to dwell on London's high diphtheria figures. With reference to the comparison of London with other capitals and large cities, to draw conclusions from a period as short as three months is obviously fallacious, therefore recourse has been had to the last three years, 1924 to 1926, to show that London's diphtheria mortality occupies a high place on the list. Taking the averages of 1924 and 1925, there are only three continental towns or capitals whose mortality-rates are higher.

Sofia	20·6	Berlin	6·2
Moscow	16·5	Paris	5·8
Rome	13·2	Vienna	4·7
LONDON	11·5	Hamburg	3·1
New York	11·47	Hague	2·4
Dublin	10·25	Oslo	2·0
Leningrad	9·6	Brussels	1·9
Chicago	7·5		

For 1926, figures for twelve European towns and capitals are available, and among these London takes the third position.

Dublin	14·6	Berlin	7·6
Budapest	12·3	Copenhagen	7·0
LONDON	11·9	Stockholm	5·5
Edinburgh	10·1	Vienna	4·2
Paris	8·3	Hamburg	1·7
Warsaw	8·2	Oslo	1·0

* The Prevention of Diphtheria, Med. Res. Council, Special Report Series No. 115.

In reference to other parts of the world may be mentioned :—

1926.		1926.	
Auckland, New Zealand	8·3	Chicago	7·4
New Orleans	8·0	Sydney	7·1
New York	7·9	Madras	1·3
		Bombay	0·54

Quarterly fluctuations are too considerable to admit of fair comparisons of figures for the single quarter of 1927 such as Mr. Maben relies on—e.g., in London the quarterly variations in diphtheria deaths ranged as follows :—

1st .. 188 .... 2nd .. 117 .... 3rd .. 82 .... 4th .. 151

As regards case-mortality, London's position, as Mr. Maben points out, and for which perhaps credit is due, appears in a more favourable light especially in 1926. This may be in part due to the infection having been less uniformly prevalent all over London, but that does not imply that the disease has been milder in form, for its incidence during the past 18 months has been markedly focal and concentrated in particular areas, especially in parts of Deptford, Bermondsey, Southwark, Lambeth, and Battersea. In these foci of infection the disease has shown no diminution of its malignancy. Possibly but not positively also London's low case-mortality *may* be attributable to a larger proportion of the notified returns being uncorrected for errors in diagnosis in London than elsewhere. But it may be hoped that efforts to secure prompt treatment which the authorities have frequently urged and the efficiency of the treatment in M.A.B. hospitals has borne fruit. Thus of the large towns the diphtheria case-mortalities per cent. may be quoted as follows :—

Fifteen years' average.		1926.	
Newcastle	6·2	West Ham	2·8
Bristol	6·2	LONDON	3·9
Sheffield	6·3	Sheffield	4·7
Bradford	6·4	Birmingham	5·1
Portsmouth	6·5	Glasgow	5·3
Cardiff	6·8	Edinburgh	5·6
LONDON	6·8	Cardiff	5·6
Glasgow	8·5	Bristol	6·0
Leeds	8·8	Bradford	6·1
Edinburgh	9·0	Liverpool	6·7
Birmingham	9·6	Portsmouth	7·0
Liverpool	10·0	Newcastle	8·0
Manchester	10·4	Manchester	8·2
New York	8·2	New York	6·4
Chicago	9·3	Chicago	8·1

There has, moreover, been a general steady decline in case-mortality throughout England and Wales in the last decade from 10·9 in 1918 to 5·8 per cent. in 1926.

A discussion of the influence of errors in diagnosis of notified cases on the attack rates, to which Mr. Maben alludes, finds place in the report on p. 22. It must, for want of more accurate information, be assumed that such faults in the returns of notified cases, reckoned as diphtheria, affect the accuracy of all the sources of information uniformly and therefore do not prejudice one return more than another.

I am, Sir, yours faithfully,

J. GRAHAM FORBES.

County Hall, S.E., July 4th, 1927.

ETHER CONVULSIONS.

To the Editor of THE LANCET.

SIR,—In your issue of June 25th Dr. Gwathmey of New York attributes the convulsions I have described during the administration of ether to the presence of congestion of the lungs in these cases, and he expresses the view that such a condition is avoidable by preliminary medication. Whilst readily admitting that any condition which interferes with pulmonary ventilation is a possible contributory factor, such an explanation entirely ignores fundamental facts which cannot be disputed :—

1. Ether has been in continual administration for 70 to 80 years, yet these convulsive manifestations were not noted until 18 months ago.

2. For 50 years ether was administered without any preliminary medication with far more oxygen limitation and in greater concentrations than are usual at the present day, yet these convulsive attacks were never observed.

3. If the condition were due to insufficient ventilation by the lungs, the clinical features would be those of asphyxia and readily recognisable by any administrator of moderate experience, whereas cyanosis only developed after the respiratory centre ceased to function, and did not precede the convulsive attacks.

4. The presence of the impurities referred to in my paper does lead to pulmonary changes, as pointed out by Prof. Storm van Leeuwen, whilst such changes are not noticeable if a pure ether is used.

It is clear that the manifestations I described are of comparatively recent development and attributable either to changes in the ether or in modern methods of administration or both, and that the whole problem of the effects of pure ether requires reinvestigation in the light of these occurrences. Premedication by reducing the amount of a toxic ether will, of course, diminish the toxic effects, but the real solution lies in the exclusion of the toxic agent.

I am, Sir, yours faithfully.

Manchester, June 27th, 1927. S. R. WILSON.

PSYCHOGENIC ASTHMA.

To the Editor of THE LANCET.

SIR,—With reference to Mr. Moxon's letter in your issue of June 18th respecting Dr. E. B. Strauss's report of two cases of psychogenic asthma (THE LANCET, May 7th, 962), I should like to point out that they seem to me to be on all fours with Rivers's often cited case of claustrophobia. I discussed this in a paper published in the *British Journal of Medical Psychology*, October, 1925, v., 92–105, where I pointed out what seems to me to be the mechanism of formation of such neuroses.

If an exceptional experience, A, engenders a powerful emotion and is at the same time accompanied by some accidental experience, B, an experience that by itself would not arouse the emotions, then the recurrence of B tends to arouse a like emotion. At first the association between B and the emotion is not very strong, but gains in strength with repeated occurrences of B, until at last it becomes so strong that B itself gives rise to the emotion. This I regard as but a specific case of the "conditioned reflex," and it also explains very well the so-called "period of incubation," so often observed in war neuroses.

In my case referred to above there was A, the air-raids which engendered emotions of distress. The simultaneous accidental experience was the bright moonshine. Long after the air-raids had stopped the moonshine gave rise to states of vague anxiety, not directly attributed to the moonshine, and which states of anxiety became gradually stronger as time went on, until they were strong enough to engage my attention as to their cause. This required but little searching and the acquired knowledge of the causal connexion soon cleared up an incipient neurosis.

In Rivers's case there was A, the snarling dog which frightened the boy ; B, the passage, or enclosed space, where the boy happened to be at the time. His fear was increased as there seemed no means of escape. Gradually, as the boy grew up any enclosed space aroused fear, and the association with the idea of inability to escape would be strengthened. The case became one of claustrophobia, which again was cleared up as soon as causal relations had been established or understood by the patient.

In Dr. Strauss's cases there was A, the treatment the boy received from his nurse, followed by the experience of suffocation, and B, certain not definitely ascertained home surroundings. Whilst the boy was in hospital—i.e., away from home—he was free from asthmatic attacks, but he relapsed as soon as he returned home again. In the case of the woman teacher there was A, the accident of falling into the water and missing being drowned, evidently accompanied by the experience of suffocation. A reinactment of the accident in dreams was followed by

asthma. The dyspnœa in these cases is but a part of the emotional disturbance.

It is, in my view, not the bringing into consciousness, as such, which produces the cure, but the intelligent understanding by the patient of the causal relation of his trouble with the original occurrence. Dr. Strauss's juvenile patient was in all probability an intelligent child. This view of mine is confirmed by Janet's case "Marie," who being a stupid peasant girl could not be cured by bringing into consciousness the original occurrence which caused her stigmata; she was not able to grasp the significance. She was, however, relieved of her troubles by suggestions that the occurrences had never happened.

I venture to think that your readers will prefer such simple explanation of Dr. Strauss's cases, which has the advantage of being based on known physiological or psychological facts as well as clinical observation, to Mr. Moxon's psycho-analytic speculation. I am, Sir, yours faithfully,

Shortlands, Kent, June 21st, 1927. A. WOHLGEMUTH.

"AN OPPORTUNITY FOR PHARMACISTS."

To the Editor of THE LANCET.

SIR,—I read the annotation on this subject in your last issue with satisfaction, because the balance was so justly held. I was present when the paper was read, and had the advantage of hearing the discussion on it.

The pharmacist, by his training, from bottle-washing to the higher flights of chemistry and botany, is usually an adaptable person. He has to learn so many things that an extra subject is hardly noticeable, but he is also faced with the necessity of earning a living. My experience, in a good-class suburban business, is that so far there is no sign of an opening for pharmacists of the kind alluded to by Dr. Burn. I say this with due respect to the author of the paper, and would add that I am not writing in my capacity as a member of the Council of the Pharmaceutical Society, but rather as an ordinary pharmacist. My personal opinion is, that the present pharmaceutical curriculum is more than adequate to meet the requirements of everyday practice. At the same time it was made quite clear, in the most instructive discussion, that if pharmacists are required to undertake the work outlined by Dr. Burn they will not be found wanting.

One speaker after another, who had been specially trained for the work, asserted that there was "no opening," and that what work there was went to central laboratories. The reduced allowance for "insurance dispensing," coupled with the high cost of living, make things very difficult for the pharmacist who has to depend solely on the so-called professional side of his business. To make both ends meet he is compelled to secure "side lines" of a commercial kind, for which there is a demand.

I need hardly add that the Pharmaceutical Society, old as it is, is none the less alert, and I agree with you that the time may come—and probably will come—when there will be a cleavage between two schools of pharmacy, but the time is not yet.

I am, Sir, yours faithfully,

Ealing, W., July 3rd, 1927. THOMAS MANUS.

ANÆSTHETISTS AND INQUESTS.

To the Editor of THE LANCET.

SIR,—The tendency to throw blame upon an anæsthetist indicates a state of mind which has parallels in the suspicion surrounding certification of the mentally unsound, and, as shown by recent legislative events, the control of the mentally defective. But it has results peculiar to itself. Fortunately the judgment of a surgeon is rarely hindered by fear of criticism in the event of an unfavourable issue, and on the whole it is well that it is so. When grave problems have to be faced, and risks to be taken, the decision must not be influenced by the possibility of the operator being called upon publicly to face an inquiry, the mere holding of which implies that his conduct and skill are impugned. The freedom from this danger allows of free discussion and, if necessary, free technical criticism from those qualified to offer it, but these advantages are absent when an inquest is given a capricious publicity undirected by a knowledge of the risks, practically negligible in the mass, that remain after the fullest care and skill have been exercised.

The demand for explanation of deaths under anæsthetics has, in fact, seriously hindered the advance of knowledge. The writer has no recollection of any inquest concerning such a death in which medical witnesses have frankly admitted that there was no pathological condition found post mortem to account for the death, and we may safely assume that such an admission would inevitably have led to the belief that the fault lay with the anæsthetist.

A certificate of death records whether any operation has preceded the fatal issue, and it is perhaps partly due to the antiquity of the surgical art that the question whether the operation has caused or hastened death is rarely raised. Anæsthetics are modern, and their introduction was marked by opposition of a peculiar kind, in which theological considerations played a part, but we cannot say how far a relic of this opposition is responsible for the selection of this one mode of death as demanding a definite pathological explanation. We, as a profession, are sometimes accused of assuming the mantle of infallibility, but in this matter the mantle is forced upon unwilling shoulders. A medical witness would risk professional ruin if he told a jury "I gave this anæsthetic with a correct technique, with every care and precaution, but the patient died, and I cannot tell you why he died."

The fact that the thymus is often found enlarged has in many cases served as a basis for explanations which satisfied coroners' juries and the public, and gave us a sense of finality which solved the immediate difficulty and arrested further inquiry. But now doubt is being thrown upon the existence of status thymico-lymphaticus, and each of the many deaths ascribed to that condition represents an unsolved problem. Prof. Carl Hart, to quote only one writer, says: "For the teaching concerning status thymico-lymphaticus began like many other teachings. At first accepted grudgingly by physicians, it has now more and more fallen a prey to uncritical application and exaggeration, and finally become a great rubbish heap upon which all conceivable morphological and functional phenomena have been thrust." (Die Lehre vom Status thymico-lymphaticus. Munich: J. F. Bergmann. 1923. P. 1.)

The observation in your leading article of June 25th, that the publicity of these inquests instils fear into the public mind, and thus increases the possible dangers of anæsthesia, perhaps contains the clue which has been obscured by that demand for material explanations which produced the hypothesis of status thymico-lymphaticus. It needs no psychologist to prove that fright can kill. But may it not be that the neglect of psychological considerations on the part of ourselves, in conjunction with an unfortunate demand from the public for physiological explanation, has led us astray from the scientific path?

I am, Sir, yours faithfully.

June 27th, 1927. OPERATING SURGEON.

INCREASE IN HOSPITAL BEDS.—During the past few weeks several foundation-stones have been laid, not only of voluntary hospitals, but also of Poor-law institutions. Willesden General Hospital is to have two new wards, one for children, and a new operating theatre. At Brixham, on a beautiful site at the edge of the town, a new hospital is being erected. The guardians at Derby for the last 14 years have realised the need for enlarging their hospital. The site of the new building is opposite the existing Poor-law institution; it is calculated that the hospital will cost over £83,000.

Obituary.

JAMES WALKER DAWSON, M.D., D.Sc., F.R.C.P., F.R.C.S. EDIN.

THE death of Dr. James Dawson at his home in Edinburgh will be deeply regretted not only by his personal friends and colleagues in Scotland, but by many who knew him only by his published work. Dr. Dawson had a shy and retiring disposition; he shunned publicity, and spent the last 20 years working steadfastly in his laboratory. The outside world saw little of him, but the charm of his personality was at once manifest to those who interrupted his labours to seek advice or help. This was never denied, but indeed was given in full measure; no trouble could be too great if its object was to further research.

Throughout his life Dr. Dawson was hampered by ill-health. He was born in India in 1870, and began his medical course at Edinburgh University as early as 1886, but was interrupted by ill-health and did not graduate till 1904. Four years later he obtained the degree of M.D., being awarded a gold medal for his thesis on Inflammation, and shortly after this he was awarded the Syme Surgical Fellowship. He was later a Carnegie Research Fellow, for a time assistant pathologist to the Royal Infirmary, and was pathologist to the Longmore Hospital to the time of his death. Dr. Dawson's main work was performed as histologist to the Research Laboratory of the Royal College of Physicians, Edinburgh; here and in the library of the College he carried out those most careful and painstaking observations on pathological histology which brought him fame. Up to 1916 neurological pathology formed the greater part of his research, in particular, disseminated sclerosis, multiple neuromata, and the lymphatics of the nervous system. Thereafter he devoted much time to the study of malignant growths. His exhaustive monograph on the melanomata, beautifully illustrated by 30 plates, ranks as a classic work of reference. With Mr. J. W. Struthers he wrote an authoritative article on Osteitis Fibrosa; his final illness prevented the completion of a paper on breast tumours. Most of his research appeared in the *Edinburgh Medical Journal;* we have often had occasion to draw attention to its importance.

Dr. Dawson was a Fellow of the Royal College of Physicians of Edinburgh, and was elected a Fellow of the Royal College of Surgeons of Edinburgh in recognition of his valuable services in the advancement of surgical knowledge. His routine surgical reports are worthy of special note. Specimens referred to him for his opinion were invariably subjected to a keen and critical examination, and exactly those points were stressed which enabled the surgeon to gauge the extent to which operation should be carried. He was one of the vice-presidents of the Section of Pathology and Bacteriology at the British Medical Association annual meeting to be held in Edinburgh next week. This year also he was to have delivered the Morison lectures by invitation of the Royal College of Physicians of Edinburgh, and he had already collected a considerable amount of data for this purpose; it is to be hoped that this material will not be completely lost to science.

During the war Dr. Dawson acted as lecturer in the University of Edinburgh, and was to have continued in this post; but few had the benefit of his teaching, since ill-health forced him to resign.

A fellow pathologist writes: "His pathological friends have to thank James Dawson for much good work, and it is sad to think that there can be no more of it. The quality was such, and reached by such thorough painstaking toil, that we all trusted and believed in what he had to say about disseminated sclerosis, the healing of wounds, osteitis fibrosa, and lastly in his monograph on the melanomata. Dawson believed in it too, for when he had got through the painful process of satisfying his own conscience that his conclusions were justified, it was not easy to get him to modify any definite opinion that he had achieved. His ally, Mr. Hamilton, will continue to produce the beautiful large sections which Dawson did so much to popularise, and his essay, Religio medici, is a permanent record of the gentle sincerity with which he lived."

JOHN LEACH, M.B., C.M. ABERD.

Dr. John Leach, who died last week at Graffham, Sussex, where he was acting as resident physician to Lord Woolavington, was a familiar figure in the North of Scotland, for he had practised for over 30 years at Beauly, his duties taking him into the remotest parts of Ross-shire. He was born at Ardersier, Inverness-shire in 1867, educated at Marischal College, Aberdeen, qualifying in 1892, when he took resident appointments at Inverness District Asylum and at the Manchester Maternity Hospital before settling in Beauly. Here he came to take a large part in public life, representing his division on the county council and serving on the parish council and school-board. He was also an active member of the county insurance and panel committees. His first association with the Territorial Service was when he was medical officer at Beaufort to the Scouts raised by Lord Lovat during the South African War, and he retained the appointment of medical officer to the 1st Lovat Scouts Yeomanry tili 1915, when for the remainder of the war he was attached to the Highland Mounted Brigade Field Ambulance at Inverness. Dr. Leach was the recipient of many marks of respect and affection on his recent retirement from general practice. He was in his sixty-first year and leaves a widow and three sons, one of whom maintains the family medical tradition at Beauly.

CHARLES GASKELL HIGGINSON, M.A. LOND., M.D. DURH., L.M.S.S.A.

Dr. Higginson, who died in a nursing home at Edgbaston, Birmingham, on June 26th, in his sixty-ninth year, was son of the Rev. Edward Higginson and was educated at his father's school at Swansea and later at London University, where he took his M.A. in 1881 with distinction in philosophy and economics. It was not until some ten years later that he entered the Manchester Medical School, from which he qualified in 1897, thereafter spending three years in resident hospital appointments and finally acting as assistant to Dr. F. R. Walters at Crooksbury Sanatorium, where his interest in tuberculosis was awakened. After settling in Edgbaston his practice developed in this direction, and he contributed freely to medical journals on such subjects as the rational treatment of capillary hæmoptysis, the cure of consumption according to the methods of George Bodington and Henry MacCormac, and the technique of staining tubercle bacilli. During the war he acted as civil surgeon to the 2nd Birmingham War Hospital. Never very robust, his activities covered a wide intellectual field; he was an earnest student of poetry and an accomplished traveller.

WALTER HENRY RYAN, M.R.C.P.I.

Dr. Ryan, who died at his home in Roade, Northamptonshire, on June 26th, was a practitioner well known throughout the county. A native of Scarteen, co. Limerick, he was educated at St. Mary's College, Oscott, and studied medicine at the National University of Ireland, qualifying in 1876 and being elected a member of the Irish Royal College of Physicians 12 years later. On returning to this country he acted first as assistant at Leighton Buzzard before practising on his own account at Hanslope and later at Roade. He became medical officer to the local rural district council and to the board of guardians, on which he served as a member for many years. No mean cricketer himself, he was a member of the county club for nearly 40 years and was indefatigable in arranging tennis tournaments on behalf of local charities. At the time of his death he was the oldest member of the Grafton Hunt. He leaves a widow and a son in the Royal Army Medical Corps.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Rear Adml. Arthur Gaskell, C.B., O.B.E., took up his duties as Director-General of the Medical Department of the Royal Navy on July 1st.

Surg.-Capt. A. R. H. Skey and Surg.-Capt. H. C. Whiteside to be Surg. Rear-Admirals.

Surg. Comdrs. C. T. Baxter, A. McCloy, and G. L. Buckeridge to be Surg. Capts.

Proby. Surg. Lt. R. Erskine-Gray to be Surg. Lt.

Surg. Lt. D. H. Kernohan to *Pembroke*, for R.N. Barracks, Chatham.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. W. J. Payne to *Victory*, for R.N. Hospl., Haslar, for 28 days' training.

Surg. Lt. (D.) W. M. Bull, to *Victory*, for R.N. Barracks, for 14 days' training.

Proby. Surg. Sub.-Lt. D. W. Bawtree, to *Tiger*, for further 14 days' training.

ROYAL ARMY MEDICAL CORPS.

Temp. Capt. W. Bligh to be temp. Maj.

TERRITORIAL ARMY.

W. C. Armstrong to be Lt.

Supernumerary for service with O.T.C.: 2nd Lt. W. E. Underwood, from the Gen. List, T.A., to be Lt. (Med. Unit, Lond. Univ. Contgt., Sen. Div.).

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. F. A. Roper, from Active List, to be Lt.-Col.

Maj. (Bt. Lt.-Col.) C. H. Lindsay, from Active List (Supern.), to be Maj. (Bt. Lt.-Col.).

Capts. D. Cameron and R. A. Quinn, from the Active List, to be Capts.

ROYAL AIR FORCE.

Wing Comdrs. to be Group Capts.: A. V. J. Richardson and J. McIntyre.

INDIAN MEDICAL SERVICE.

Lt.-Col. W. D. A. Keys to be Bt. Col.

Maj. J. Scott to be Bt. Lt.-Col.

Capt. C. J. L. Patch to be Maj.

Lt. H. W. Mulligan to be Capt.

SMALL-POX LEAVE RESTRICTIONS.

A Fleet order announces that restrictions, on account of small-pox, are applicable in Abercarn, Abersychan, Blaenavon (Mon.); Annfield Plain, Auckland, Brandon and Byshottles, Chester-le-Street, Crook, Durham, Easington, Felling, Gateshead, and Hetton (Durham); Ashington (Northumberland); Bentley-with-Arksey, Conisbrough, Doncaster Borough and Urban District (Yorks); and Derby.

DEATHS IN THE SERVICES.

Surgeon Rear-Admiral George Albert Dreaper, Extra Hon. Surgeon to the King, who died on June 28th at the Royal Naval Hospital, Haslar, within a few days of 64 years of age, was educated in Dublin, and entered the Royal Navy in 1884. He was staff surgeon of the *Magicienne* during the Jubaland expedition, 1900–01, when he was landed in charge of the military hospital, and received the appreciation of the Admiralty, the General African Medal, and the Jubaland clasp. In the Somaliland expedition of 1904 he was fleet-surgeon of the *Fox* in command of the medical staff, and was landed for the capture of the Mullah's stronghold at Illig. For this service he was mentioned in dispatches, and received the General East African medal with clasp for Somaliland. From 1908–10 Fleet-Surgeon Dreaper was in charge of the surgical wards at Chatham Naval Hospital, and was promoted to Deputy Surgeon-General in 1913. Later he took over the charge of the surgical wards at the naval hospitals at Plymouth and at Hong-Kong. He was promoted to Surgeon Rear-Admiral in 1919, was made C.B. in 1920, and was in command of the Royal Naval Hospital at Chatham until 1923 when he retired. In 1910 he married Constance Amy, daughter of Mr. Henry de Blaquiere, J.P., of Fiddane, Gort.

Col. John Smyth, I.M.S., retd., died at his residence, Apsley-road, Clifton, on July 2nd. He graduated M.D., M.Ch. R.U.I. in 1879 and received his first commission in the Army in 1881, reaching the rank of Major in the I.M.S. in 1893, Lt.-Col. in 1901, and Col. in 1911. He served with the Soudan Expedition, 1885, and was present at the actions of Hasheen and Tofrek; and the destruction of Tamai, where he was wounded. (Medal with two clasps; bronze star.) He had also been medical officer to the Maharajah of Mysore and Honorary Surgeon to the Viceroy.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 29TH.

MINISTRY OF HEALTH VOTE.

THE House went into Committee of Supply on a vote of £12,943,593 for the salaries and expenses of the Ministry of Health. Mr. CHARLES EDWARDS was in the chair.

Mr. NEVILLE CHAMBERLAIN (Minister of Health) said that this year there was an increase in the vote of a little more than £1,105,000, but he did not imagine that he would be accused of extravagance, because the increase was due to causes which operated automatically, and was, moreover, brought about by policies which had been approved in all quarters of the House. Some £960,000 was accounted for by an increase in the number of houses upon which subsidy was paid, and there was a further £171,000 on the grants-in-aid for health purposes, and still another increase of £91,000 in respect of the cost of administration due to the additional staff required for the purposes of the Contributory Pensions Act. The amount provided for housing—£9,340,000—was nearly half of the total estimate amounting approximately to £19,500,000. In the five years preceding the war the average number of houses built in this country was about 61,000. Taking the last three years—in each case the 12 months ended March 31st—the number built in 1925 was 137,000; in 1926 it rose to 173,000; and in 1927 to 217,000. That was really an astonishing, a prodigious effort on the part of this country which he did not think could be paralleled anywhere else in the world. (Cheers.) The number of houses which had been added to the common pool was so great that as it proceeded its effects would be felt through every class of the population, and he felt confident that they were approaching the time when they might hope to see some much more active progress made with the improvement in the conditions of the slums. The cost of the new houses, however, appeared to him to be far too high, and the problem before them at the moment was to see how that cost could be reduced. There were two ways by which it might be reduced; one concerned the size of the house. There was very little doubt that the rents which had to be charged for the bulk of the new houses were inflicting a very great strain on those who were paying them, while they made it impossible for many others to obtain the accommodation which they desired in a new house, because it was altogether beyond their means. He was not in favour of lowering the standard of housing, but it was no use to blink facts, and while it was very easy to be eloquent about the difference between the houses occupied by the rich and the poor, as a matter of fact they could not divide the population by a sharp line into two categories of that kind. Everything must be adapted to the question of means, otherwise people would come to disaster. He thought that it was a mistake to assume that every family wanted a bigger house which not only meant more rent to pay, but entailed more work in keeping clean and warm. Local authorities were finding that they were getting towards the end of that section of the community which could pay the rents of houses such as they were now erecting and that being so he thought they were wise in remembering that what they had to compare was not a small new house with a large new house, but a small new house with the houses in which people were living now, or the rooms in a house in which they were living now, and that if they built houses which contained all the necessaries of life, but with somewhat smaller accommodation than was contained in the houses which they had been building lately, they would probably meet the wishes of the greater number of their inhabitants. Events had completely justified the predictions he had made last December, when he asked the House to approve the draft Order under which the subsidies payable under the Acts of 1923 and 1924 would be reduced as from October next by an amount which was equivalent to a capital sum of £25 per house. The prices of non-parlour houses which before the commencement of the withdrawal had ranged from £440 to £450, fell immediately to the neighbourhood of £425 for houses with exactly the same accommodation. Since then there had been a still further drop. Last month the average size of the houses was distinctly smaller and the prices had actually gone down to something below £400.

Town Planning.

Public appreciation of the value of town planning seemed to be generally increasing. It saved unnecessary and wasteful expenditure in the future and at the same time preserved amenities and conveniences for the public. At the present time some 2,700,000 acres were covered by town planning and regional planning schemes. The development of regional planning was of the greatest importance, because it was obvious that to plan a limited area without regard to

what would happen in the surrounding areas must necessarily mean a good deal of wasted time and might lead to the adoption of plans which subsequently would have to be altered. Therefore he was glad to know that the adoption of regional planning which involved the coöperation of a great number of local authorities was proceeding so rapidly and smoothly, and he thought that further progress in that direction would be very valuable for the country as a whole. In those schemes and otherwise local authorities were beginning to make much greater provision for playing fields. In this connexion steps had at last been taken to set up a Regional Committee for Greater London which presented problems which were unique in the constitution of its local authorities and in the extent of its area. Another matter to which he wished to refer was the preservation of London squares. The Government had accepted the view of the London County Council and proposed to set up a Royal Commission to go into the whole question. With regard to national health insurance he would like to say something about the additional benefits provided out of surpluses disclosed upon the second valuation of approved societies. Nearly £24,000,000 was shown to be available for distribution under the second valuation, but out of that sum over £11,000,000 had already been allocated by the societies for additional cash benefits, leaving about £12,000,000 available for non-cash benefits. The latter sum was increased by the State grant and interest until it had reached the astonishing sum of £18,000,000 available for distribution in treatment benefits during the five years covered by the surpluses under this valuation. That meant that altogether some £3,750,000 a year could be and was being spent on these additional treatment benefits. The societies had allocated to dental benefits as much as eight times the amount they were able to allocate under the first valuation and to ophthalmic benefit as much as 12½ times the amount they had formerly allocated. In connexion with dental benefit a scheme had been arranged under which for the most part the societies paid 100 per cent. in the case of conservative treatment of teeth and 50 per cent. of the cost of dentures and they had set up as recommended by the Royal Commission a regional dental service consisting of one principal and five regional dental officers whose duty it was to advise in cases of dispute between approved societies and dentists. That had required and would require a large number of examinations of the persons concerned. Up to the present there had been something like 2600 references to these regional officers. The greater part of those references had already been cleared, but a certain amount of delay had been experienced owing to the fact that nearly 40 per cent. of the insured persons had failed to keep their appointments with the dentists. He hoped that as insured persons got more experience their attendances would improve, and he felt very well satisfied that the provision of this additional benefit, under which over 13,000,000 people, many of whom had never been in the hands of a dentist before, would now have their teeth attended to, would mean greatly improved health on the part of insured persons and as a consequence a decrease in the claims upon the funds of the approved societies. The International Labour Conference which had just concluded, and which represented about 38 countries, had adopted a draft convention which was based principally on the same principles as our own health insurance scheme, and he had hopes that the majority of the countries, at any rate, would ratify the convention.

Improvement in Public Health.

With regard to the state of the public health he was glad to be able to give a good report. There were two general tests which they applied—namely, the general death-rate and the infantile mortality-rate—and in both cases there was an improvement. Last year the general death-rate was 11·6 per 1000, compared with an average of 12·2 per 1000 in the five years preceding, and the infantile mortality-rate, which had been 76 per 1000 in the preceding five years, had come down to 70. This denoted a general improvement in the physique of the infant population and also an increase in the understanding of the responsibilities and duties of motherhood. One could not say too much in praise of the great system of maternity and child welfare centres which were now spread throughout the country and on which an immense amount of devoted voluntary effort was being expended. To that he thought they must ascribe the continued improvement in the infantile mortality-rate, with which they had so much reason to be satisfied. In other respects the health of the nation continued to improve. There was a steady decline in the mortality due to tuberculosis, to scarlet fever, and to typhoid fever. He wished he could say as much for cancer. He was sorry to say that the deaths from cancer continued to increase and he was not able to announce any new discovery which gave them hope of being at an early date able to cope with that disease. But their knowledge was increasing all the time, and he had little doubt that the day would come—and he hoped it was not far distant—when they would be able to put cancer among those diseases of which they considered themselves the master. The records of small-pox in this country were becoming very alarming. In 1922 there were 973 cases; in 1923, 2500; in 1924, 3800; in 1925, 5300; in 1926, 10,100, and this year up to the end of May they had had 8700 cases. Those were for England and Wales, including London; they did not include Scotland. Fortunately the type of small-pox at present was of a very mild character, but one was always afraid that they might see a recurrence of that very virulent form of which they had had experience before and which was one of the most deadly diseases of which they knew. He had set up a committee to inquire into the question of vaccination, and he would not say any more on that subject, except that it was quite clear from these figures that the extent of the disease was now assuming serious proportions and even though mild in character it was inflicting an amount of pain, suffering, and loss which was preventable, and ought to be prevented, and presently they would have to take some further steps to see if they could not diminish it. He wondered whether the Committee realised the part which this country was playing in measures which were taken internationally for the prevention of disease and the improvement of health. The League of Nations had a Health Committee upon which this country had a representative and upon which there was also a representative of India. He hoped that in future there might also be representatives of other parts of the Empire. This Committee was engaged at the present time in two pieces of work which were certainly of direct interest to us as a country and to the British Empire. One of them was concerned with the establishment of an Epidemic Intelligence Centre at Singapore. The sanitary administration of the ports in the Far East was a particularly difficult problem because each one of those ports was surrounded by great areas in which the conditions were such that epidemic diseases were always present, and it was of the very first importance to prevent the spread of diseases like yellow fever, plague, or small-pox by communicating information from one sanitary port officer to another. By the generosity of the Rockefeller Trustees this Epidemic Intelligence Centre had been established at Singapore, and thanks to that and the introduction and development of wireless it was now possible to convey information with great rapidity and at an extremely low cost, and he thought the results were invaluable to British interests generally and to British shipping in particular. There was also the work which was being done by the Health Committee of the League of Nations in the investigation of the prevention of malaria. A great deal was already known about malaria, thanks largely to the researches of British investigators. They knew that malaria could be stamped out in particular localities, as had been done in Panama, but these measures were very expensive, and what the League was doing now was an attempt to discover some new methods of prevention which might perhaps be less intensive in their scope, but which would be less expensive and could therefore be put into operation over larger areas. At the Paris Sanitary Conference, held last year, and the Pacific Health Conference at Melbourne, this country was very ably represented by officers of his department.

Hygiene and Tropical Medicine.

He had finally to mention two projects, both of first-rate importance, which were now proceeding in London. In 1920 a committee was set up under the chairmanship of Lord Athlone by the then Minister of Health, Dr. Addison, and one of its recommendations was that there should be established in London a school of hygiene and tropical medicine. That school was now being built. The Rockefeller Trustees, who took the greatest interest in all matters of international health, had contributed a sum of $2,000,000 and the British Government had made itself responsible for the maintenance of the school when it was completed. The school was of the greatest interest to the British Empire because there were so many portions of our Empire in the tropics whose future prosperity depended largely on our power to control tropical diseases which at present took such a tremendous toll of our people and of the native populations. They believed that this school would form a centre to which could come those who were proposing to embark on a career as medical officers of health or medical practitioners in the tropics. They would be able to see there clinical material actually suffering from the tropical diseases which they would find when they got to their destinations and where also they would be able to study those general principles of public health which governed all administration of the kind whether in the tropics or in temperate climates.

Post-Graduate Medical Study.

The other project was also one of the recommendations of the Athlone Committee. It was that there should be established in London a post-graduate medical school. Unfortunately for one reason or another this

recommendation had never yet been carried out, but now he thought they were approaching a time when they would see it accomplished. Some little time ago he had set up a strong committee of physicians and surgeons under his own chairmanship to consider what was the best way of carrying the proposal into effect. The committee laid it down that it was not possible to combine in one school undergraduate and post-graduate teaching, and that was a conclusion which he thought was supported by all expert opinion. Therefore they had to consider whether they should contemplate the building of a new school or whether it would be possible to adapt some existing institution. They decided against the building of a new school, because that meant, in order to obtain the necessary clinical material, the building of a hospital with 400 beds which would have involved not only a very large capital expenditure, but also an annual liability for the maintenance of the hospital. The Committee therefore devoted themselves to an examination of various existing institutions, and they came to the conclusion that they could find what they wanted in the West London Hospital at Hammersmith. That was a hospital which had a long experience of post-graduate teaching. It had space into which it could extend, so that the necessary lecture rooms and laboratories and additional beds could be provided, and the scheme had been accepted in principle by the authorities of the West London Hospital. At the present time the buildings were being examined by technical experts with a view to seeing how they could be adapted and extended so as to make them available for this purpose. If this scheme could be brought to a conclusion it was going to be a great thing for the medical services of this country and of the Empire, and he might almost say of the world. One of the difficulties to-day was that medical practitioners who might have had a magnificent training before they entered into practice went down into some remote part of the country and found themselves unable in any way to keep abreast of the most modern work. He hoped that in this school it would be possible to give short refresher courses to general insurance practitioners.

Mr. MACLAREN: Would it be compulsory?

Mr. CHAMBERLAIN said that he was not contemplating that at present; obviously financial difficulties would arise. He hoped, however, that practitioners would avail themselves of it as it became further known. More than that, it would be a meeting place where medical men would come from all parts of the Empire to exchange ideas and experiences, to see what the latest experiments and the latest methods were, and what success had attended them. He found that in America also a project of this kind was welcomed most warmly. Many American doctors liked from time to time to come over to Europe to see what was being done here and to check their own experience against European experience. The completion of a scheme of this kind would mean the expenditure of large sums of money, but when it was realised what a great conception this was and what a vast influence it might have in raising the general standard of medical practice, not only in this country, but in other countries, he felt confident that the funds that were necessary would not be wanting.

Dr. VERNON DAVIES: Would this hospital be built and financed by the State or privately?

Mr. CHAMBERLAIN: I am not at present contemplating that it should be financed by the State.

Dr. DAVIES: What connexion will the Ministry of Health have with it?

Mr. CHAMBERLAIN: It is possible that a contribution might be given to such a hospital from the educational point of view, and that would bring the Ministry of Health into very close contact with it.

Mr. CRAWFURD moved to reduce the vote by £100.

Criticism of the Ministry.

Mr. RHYS DAVIES said that some sections of the community were very dissatisfied at the present position in regard to deaths of women in childbirth. He was informed that about 3000 women died from that cause every year in this country, and he would like to know whether London was better placed in regard to convenience and technical skill in dealing with maternity cases than the provinces. If that was so, he would urge the Minister to do something to save their womenfolk in the provinces and to see that they had the same facilities which were provided for the women of London. As regarded the question of housing he thought that the Ministry of Health ought not to concentrate on reducing the size of houses, but rather on reducing the cost of building them. The Minister had said that the cost of houses was too high, but he had not told the Committee what he was going to do to reduce the cost. He was glad that regional dental officers had been appointed to check the work of the dentists, because he was convinced that a few of the dentists even now did not play the game with approved societies. Complaints from some quarters were so strong that some of the approved societies were already thinking of diverting some of their surplus funds for use in other directions. If some of the dentists and opticians did not treat the societies better he would make it his business to see whether other additional benefits could not be established in order to divert the funds from those purposes. He must say, of course, that it was only a small section of the dental and optical professions that he complained about. The work of regional dental officers had been made very difficult, and there were many complaints of delay. He did not see how those delays were to be avoided. The regional medical officer could call a patient to him during the daytime, because he was on the sick fund and not at work. But in the case of the insured person who required dentures he could only attend in the evening, and this created a problem which he trusted the department would inquire into. Some approved societies were not at all satisfied with the arrangement whereby a person suffering from anything connected with the eyes was sent automatically by the medical practitioner to the ophthalmic surgeon. They were not satisfied that the ophthalmic surgeon should have a fee of one guinea for giving advice that ought in some cases to be given at a very much cheaper rate. It would destroy the confidence of approved societies in the work of the medical profession if the panel doctor automatically referred an insured person to the ophthalmic surgeon, and a fee of a guinea had to be paid to the latter for his work. It was also stated—he did not know how far the statement was justified—that optical practitioners claimed from 100 to 300 per cent. profit on the spectacles they sold. At any rate, the Minister ought to give some attention to the charges that were being made. He would also do well to inquire into the charges made for surgical appliances to members of approved societies. The Labour Party welcomed any new projects with regard to research into diseases, or with the idea of giving higher and better education and greater facilities to medical practitioners to improve their knowledge for the benefit of the health of the community. But what they would like to know was the extent to which the Ministry of Health intended to back up those projects financially. National Health Insurance was proceeding smoothly, and the work was being performed, as far as he knew, by the medical profession as a whole very well indeed. But he would like to see the Minister doing something beyond merely paying away benefits. He should do something to aid research work, and they had surely reached a stage when a sum of money should be made available for that purpose.

Health Insurance and Preventive Medicine.

Lieut.-Colonel FREMANTLE said that so far as the fees of ophthalmic surgeons were concerned he was certain that such matters would be rightly arranged between the Ministry of Health on the one side and the medical profession on the other. The medical profession would be the first to back up the plea put forward by Mr. Davies for research. He would endorse any proposal for giving more help to the Medical Research Council, or to research generally, but it would be unfair not to mention that that research arose out of the National Health Insurance scheme. It was true that they should look beyond the relief which had been provided by that scheme. When they looked at the larger and wider object aimed at specifically in the Act—namely, the prevention of disease—it had to be admitted that the whole insurance scheme had been a dead failure; it had not resulted in the prevention of disease in any way, and it did not tend in that direction. It was only in so far as they might be able in future administration to correlate the system of the insurance scheme with that of preventive agencies throughout the country that they could hope for any marked improvement. Poverty was one of the three essential elements in the causation of ill-health; the other two were ignorance and carelessness. It was quite certain that grinding poverty was at the bottom of a large amount of ill-health at the present time. If they could do away with that poverty for which the individuals were really not responsible, as had been largely done by the Widows, Orphans, and Old Age Pension scheme, they were going a long way towards improving indirectly the health of the community. The supply of houses was still inadequate. By the middle of 1930, if they continued to build at the present rate, they would have the population housed on much the same conditions as in 1911, with some improvement. But in 1911 in England and Wales there were 3,200,000 persons living in overcrowded conditions, more than two to a room. That condition of overcrowding continued now. The conditions in certain parts of London were appalling, and they had to be tackled; they were no less difficult than the task of overcoming the mere lack of houses, but they had to take up the question. If they read the reports of medical officers of health throughout the country they would find that during the last ten years they had skimmed very lightly over the question of the dilapidated house. They had done so because when they had reported houses as not fit for habitation no action had been taken; the local authority did not dare to take action. He hoped that this question would be taken up with increasing energy

by the Ministry of Health as the number of houses built became more adequate. He also suggested that the Ministry at least once every five years should call for a housing survey by the medical officers throughout the country, not only of the individual areas, but also of areas grouped together under the county councils. Any idea that they had come to the end of the housing problem merely because they had such a fine record as the Minister of Health had put before them that day would be grossly misleading, and he hoped that they would continue to take an active part in trying to arrive at a solution of this seemingly interminable problem.

Use of Accumulated Funds.

Mr. BRIANT said that there were many directions in which he wished to see the accumulated balances of the approved societies used. Any medical man would support him in the statement that a very large number of women who died in childbirth, or who lived on with enfeebled constitutions, could be saved from death or ill-health if they had proper medical care and had certificated midwives to attend them. He would like to see these balances used to make definite provision for the proper nursing and care of women in that condition. In his experience a large number of men and women who had not recovered from the direct effects of illness returned to work before they were fit. This meant enfeebled constitutions, if it did not actually reduce their years of life. He thought in time some way might be devised by which every worker should have the opportunity of being sent away for at least a month on a doctor's certificate, and by which funds should be provided to keep the family in the condition in which they were kept while the wage-earner was fully employed. He wished to make it clear that as a layman weighing up the evidence he had long been convinced that on the whole vaccination was a preventive of small-pox, but he was bound to add that recently there had been some statements which were at least disconcerting, particularly with regard to the possible connexion between encephalitis and inoculation. He was not satisfied that they were getting all the facts. If anything would deter people from vaccination it was a doubt as to what effects it might produce in their children. He understood that the Andrewes Committee made a report which was in the hands of some French people and had been published by them, but had never been submitted to the English public. That report ought to be made public here. They had a right not to wait for the result of the inquiry which was now being held, but to ask for some preliminary report from the Committee giving information as to the cases of encephalitis which had occurred within a period of two months after vaccination. He was disturbed the other day when the Minister of Health in answer to a question said he saw no reason why the report of his own medical officer with regard to the conditions in the hop districts should be issued. He (Mr. Briant) had visited the hopfields, and some of the conditions were disgusting and almost beyond belief. He hoped that the Minister would be able to give some more information on this subject. He hoped that whatever the Ministry might do in the way of research they would do it thoroughly. He hoped that they would not spare money in this matter, for if they could save the health of a single person the community would get the money back in a few years' time. He had every confidence in the Minister who was keen on these subjects himself, and he hoped that the right hon. gentleman would give some encouragement to those who felt that the opportunities for good of the Ministry of Health were probably unequalled by any other Ministry.

Small-pox Difficulties.

Dr. VERNON DAVIES said that the impression which he had gained from the speech of the Minister was that the outlook in regard to cancer was very much better than it had been, and that the right hon. gentleman almost ventured to prophesy that within a more or less reasonable time they would have a cure for that disease. They hoped that that was so, but he thought that it was much too strong a statement to go forth to the public at the present time. Very good work was being and had been done, but at present it must be emphasised again that the only chance for a patient with cancer was early and complete operation. He would like to ask some questions in regard to the post-graduate hospital. Most of the London hospitals and many provincial hospitals had post-graduate students. Was the new hospital going to become a State hospital for post-graduate study, not confined to medical men in this country, but open to medical men of all nations? Would a fee be charged to these medical men? That was rather an important point, because one would like to know whether it was the beginning of the State control of medicine or of a State medical service, or if it was simply the State helping medical men to provide facilities at a low cost to themselves. They had such facilities at the present time provided they were willing to pay for them at most of the London and provincial hospitals. During the year ended April 2nd last there had been 12,922 cases of small-pox notified in this country; the deaths registered during the year ended March 31st from small-pox were 33; this year there had been so far 28 deaths, 21 of unvaccinated people and 7 of people vaccinated in infancy; in the county of Durham there were 20 cases of small-pox in 1924, 1138 cases in 1925, and 6645 cases in 1926. There were also 9 cases in Hendon, of which 5 were fatal. These figures showed that small-pox had been definitely increasing in this country in the last few years from 2504 cases in 1923 to 12,922 in the year ended April 2nd, 1927, and there had been a steady increase in the death-rate from this disease. In 1914 there were 4 deaths; in 1915, 13 deaths; in 1916, 18 deaths; in 1921, 5 deaths; in 1922, 27 deaths; in 1923, 7 deaths; in the year ended March 31st, 1927, 33 deaths; and this year so far there had been 28 deaths. One also found that in 1924 there was an outbreak of small-pox in 148 separate districts in this country. That meant that we were gradually but surely advancing towards an epidemic of small-pox. Fortunately the disease had been of an exceedingly mild type, but that had made it much more difficult for the local authorities to deal with the earlier cases and to prevent the spread of the disease. He thought that the Minister of Health had a very definite responsibility in this matter, and he suggested that the Ministry were not adequately carrying out the powers conferred upon them in dealing with this danger. The Minister by his control over boards of guardians and other local authorities in health matters had a very definite power, both moral and financial. In 1924 there were only 47·5 per cent. of successful vaccinations, 37·1 per cent. of conscientious objectors, 5·4 per cent. died unvaccinated, and 0·2 per cent. were insusceptible. There was a balance of 10 per cent. unaccounted for. This 10 per cent. probably consisted of children who had escaped the meshes of the vaccination officer. They might as well put the matter quite plainly, and he blamed the Minister for not seeing that the Vaccination Act was properly carried out. Under the Act of 1898 a conscientious objector was given a chance of declaring that he conscientiously believed that vaccination would be prejudicial to the health of his child, but it was made rather difficult, because he had to appear before two justices or a stipendiary magistrate or a metropolitan magistrate in order to get an exemption certificate. The result was that the number of exemptions kept fairly steady; but in 1907 a new Vaccination Act was passed which made the procedure much more simple for the conscientious objector. The result was that in 1908 63·2 per cent. of children were successfully vaccinated, but in 1914 the figure had come down to 44·6 per cent. and in 1922 it was 40·3 per cent. One point to be noted in connexion with the statistics was that when small-pox occurred there was a larger number of successful vaccinations, but a year or two after people became less frightened and did not bother. He entirely disbelieved in these conscientious objections. In very few cases were they real. He found very often in his practice that parents who had originally stated that they had a conscientious objection were quite willing to have their children vaccinated when they wanted to emigrate to America. In a way he did not regret the attitude of certain people to vaccination because some people were so bigoted against vaccination that the only thing that would cure them was a big epidemic of small-pox with a high fatality-rate. It was a terrible thing to expect but so far as he could see it was bound to come. When the Minister found from his own statistics that things were not being properly carried out it was his bounden duty to put the law into operation and to exert pressure on the boards of guardians and local authorities. He would draw attention to some remarks in the report of the Chief Medical Officer of Health for 1925–26:—

"It is regrettable to have to record that the spread of the disease in the north-east counties was due to some extent to the failure of two sanitary authorities and their medical officers of health to take adequate steps to control the disease within that district."

Had those medical officers of health been reprimanded or dismissed? Again, had anything been done in regard to these cases:—

"One ill-administered district in the Tyneside area caused the malady to spread into eight other districts in the vicinity."

"Delay in the removal to hospital of a considerable number of cases inevitably led to the spread of the disease from the patients left at home."

If the medical officers in certain districts were neglecting their work, because that was what it came to, the Minister of Health, seeing that he paid half the salary of those officers ought to take steps to regulate the situation. He was speaking against his own profession, but no medical man had a right to undertake definite responsibilities affecting the health of the community unless he discharged his duty to the best of his ability. He recognised that in certain cases medical officers had to deal with recalcitrant local authorities or boards of guardians, but at the same time they had a definite responsibility to the community. He had suggested that Government lymph should be sold to all practitioners who desired it, because it was very pure and undoubted

the best lymph in the country. It was very successful, because in 1924 there was a case success of 99 per cent. with primary vaccinations, which was a very high percentage. His experience in practice was that it was impossible to get lymph from any firm which was comparable in any degree to Government lymph. When he became a public vaccinator and started to use Government lymph he got magnificent results with all his public cases, practically speaking never having a failure. In a short time he found his private patients coming and saying that they would rather be vaccinated with Government lymph. Vaccination was the only remedy for small-pox. It had the overwhelming support of the medical profession throughout the world. We showed ourselves the weakest country in the world in allowing conscientious objections. The sooner the people of this country realised that under strict antiseptic precautions that there was practically no danger in vaccination, but that on the contrary it would prevent small-pox, the sooner would this country get back to the happy state of affairs which existed some years ago when small-pox was practically wiped out from our midst.

Problem of the Rheumatic Child.

Dr. DRUMMOND SHIELS said that while he thought it was true to say that the medical profession as a whole still believed very strongly in the efficacy of vaccination, he also thought that there was some change of opinion in regard to infant vaccination. He had come to the conclusion seriously that the time was ripe for another inquiry into vaccination law. In some respects there was considerable laxity, enforcement was not easy, and he thought that most medical men would welcome another impartial inquiry so that the vaccination laws might be put upon a modern and proper footing. The special subject to which he wished to draw the attention of the Committee was that of the rheumatic child. This matter had been an anxiety to the medical profession for many years and recently active steps had been taken to grapple with the problem. The British Medical Association set up an expert committee in 1924, and this committee had issued two reports. The Medical Research Council had also been studying the subject and had investigated conditions in London and Glasgow. That Council had also published an interesting report. Sir George Newman and many medical officers of health had repeatedly called attention to the ravages of this disease and to its very important social and economical effects. Acute rheumatism or rheumatic fever in children was followed in a large number of cases by heart disease which, if it did not end fatally, might leave the child more or less incapacitated for the ordinary occupations of life. While there were no figures covering the whole country, it had been shown that in particular areas 10 to 15 per cent. of the children at 12 years of age were affected with rheumatism. Therefore the number in the country as a whole must be very large. It was a tragic spectacle to see these children come to adolescence carry on at ordinary work and then break down and have to go into hospital. From hospital they went back to work again, and the same process was repeated, and unless they were fortunate enough to get a very long rest, or had a very light occupation, this ended in early death. The prevention of the disease was, of course, of the first importance. Unfortunately the specific organism had not yet been discovered. Frequently the condition was associated with sore-throat, adenoids, and enlarged tonsils, and ample facilities for the treatment of these conditions were very desirable. It seemed that environment had the main effect in this disease. It rarely attacked the children of the well-to-do, and its incidence was almost entirely on poor children. The very poorest children, strange to say, did not suffer nearly so much as the class immediately above, probably because in the very humblest sections of the people there was a very drastic system of the survival of the fittest, and those who survived had a very great capacity of resistance. There was no definite feature of the environment which one could say was really the main cause of the disease. The question of housing, especially the dampness of houses, school conditions, and many other things had been investigated, but there had been nothing very definite discovered with regard to particular items of environment. There was also no convincing evidence of heredity in connexion with this disease, the similarity of environment and contagion accounting for the cases which appeared to suggest heredity as a factor. He trusted that the Minister would encourage the Medical Research Council to go forward with research into this disease, for until they discovered the specific cause they would not be able to have effective prevention, which was what they most sought. Until they had that prevention they must make all necessary arrangements for dealing with those who actually had the disease. Not only were medical men and those bodies he had mentioned taking a keen interest in this matter, but he was glad to notice that London was giving a very good lead to the country. He thought it was to the credit of the London County Council and the Metropolitan Asylums Board that they had given this lead to the whole country by the provision of special hospital accommodation for cases of acute rheumatism. The London County Council, when deciding this matter, had 1500 cases of children absent from school on account of these rheumatic conditions. They had conferences with the Metropolitan Asylums Board and the Ministry of Health, and the latter first sanctioned the provision of 60 beds, then 16, and he understood that 350 more were at present being arranged for at Carshalton. It was estimated that no less than 10,000 children in London were suffering from these conditions, and that implied 25 per cent. of chronic invalidity. Surely it was only humane and wise to deal with this matter as the London County Council were dealing with it.

Special Rest Homes.

This disease could only be effectively dealt with by establishing the special rest homes which the Council were setting up, because the interesting point about this condition was that when it arose if sufficient rest was available, and the child was not hurried back into activity prematurely, there was an excellent chance of its escaping the development of heart disease, and the consequent permanent incapacity. While this was the position in London, he would like to ask the Ministry of Health what was the position in the provinces. Were the local authorities being urged to provide similar treatment? Many local authorities had not the facilities or the accommodation except in connexion with isolation hospitals, which were not particularly suitable for this purpose. Many of them had no money to spend in providing new accommodation, and a large number of these cases had to be treated throughout the provinces in voluntary hospitals, either those for sick children or general hospitals. A few years ago the Ministry granted £500,000 to voluntary hospitals. While they awaited some satisfactory method of dealing with voluntary hospitals he would like to know if the Minister of Health had considered, or would be prepared to do so, the giving of a grant earmarked for these cases to enable the provincial hospitals to provide extra accommodation of this special kind? It could not be too often emphasised that the percentage of cases developing heart disease could be greatly reduced. There were good authorities who declared that at present 50 per cent. of cases of acute rheumatism in children developed heart disease, and that figure must be greatly brought down. Another suggestion had been made that this disease should be made notifiable. It was well-known that in all matters of research statistics were most important, and these particulars were difficult to get unless the diseases were notifiable. Hospitals should arrange with local medical practitioners for the after-care of these children when they left hospital. He would like to see this subject linked up with the orthopædic treatment of children. In this matter the Minister of Health had been coöperating with county and county borough authorities. The treatment of orthopædic cases was that of those who were externally disabled, while the acute rheumatic children were correspondingly internally disabled. It had been estimated by the best orthopædic authorities—they must pay a tribute to Sir Robert Jones for the work which he had done on this subject—that 85 per cent. of these disabled children, many of whom were put into cripples' homes and stayed there all their lives or languished at home, a burden to themselves and to the community, could be rendered capable of self-support if taken in hand soon enough and given the wonderful surgical treatment which was now available from orthopædic surgeons. He would also like to say a word or two in regard to maternal mortality. It was certainly a very difficult problem, and it was not altogether easy to understand why the figures remained as they did. He thought they must agree, however, that the prenatal condition of the mother had a great deal to do not only with the maternal mortality but with the infantile mortality. The larger individual causes of infantile mortality were premature birth and congenital debility. Greater attention to the antenatal condition of the mother, and especially to seeing that she had adequate nourishment, would almost certainly help to diminish maternal mortality. They had managed to reduce practically all other mortality figures so much that it was unfortunate that on this one point they seemed to have failed. They had not yet got the whole reasons, though they knew many of the contributory causes. In regard to cancer he would like to ask the Minister what he thought about publicity. Some local authorities in this country—and in America this has been done to a very great extent—had launched a publicity campaign pointing out to their citizens the early symptoms of cancer and telling them in simple language what were the first signs, and emphasising the ease with which a cure can be secured if early treatment is sought. Some people said that it would spread a fear of cancer and do more harm than good, but that was not the belief of the surgeons, or of the people who were most in contact with this disease, and it had not been the experience of the local authorities when it had been tried. It was very desirable that this

country should make, as it was able to make, a good contribution to the international common pool of health activity at Geneva, because they had amidst all the other rivalries of the nations and the sordid competitions of the different peoples this noble rivalry and competition—the rivalry to contribute the most possible to the store of knowledge of the laws of health.

After further debate,

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that he had not time that night to reply to the many interesting points raised in the debate. He wished to make one observation on the hospital for post-graduate medical education, because he did not want Dr. Davies, who he knew had great influence, or any other member, to think that there was any foundation for the idea that this was to be a State institution. As a matter of fact the institution was already acting under the auspices of a committee of which the President of the Royal College of Surgeons, the President of the Royal College of Physicians, the representatives of the chief medical schools, and leading members of the medical profession like Lord Dawson, were members. This institution would be in the same position as the others, and there was no intention to start a State institution of the kind.

The further discussion of the vote was adjourned.

Committee on Solicitation Laws.

Viscountess ASTOR asked the Secretary of State for the Home Department if the promised committee of inquiry on the Solicitation Laws had yet been appointed.—Capt. HACKING (Under Secretary for the Home Office) replied: It is proposed that the terms of reference of this committee shall be to inquire into the law and practice regarding offences against the criminal law in connexion with prostitution and solicitation for immoral purposes in streets and public places and other similar offences against decency and good order, and to report what changes (if any) are in their opinion desirable. My right hon. friend hopes to complete at an early date the selection of members to serve on this committee.

THURSDAY, JUNE 30TH.

Vaccination Leaflets in Schools.

Mr. GROVES asked the President of the Board of Education whether his attention had been called to the action of the local education authority in Monmouthshire in distributing a four-page leaflet, printed and published by an insurance company, advocating vaccination in the local schools, and whether, in view of the fact that propaganda on controversial subjects had not been allowed by the Board to be introduced into the schools which received Government grants, he would instruct the local authority to refrain from circulating leaflets of this nature.—Lord EUSTACE PERCY replied: I am in communication with the local authority in regard to this matter.

Stagnant Pools and Mosquito Breeding.

Mr. DAY asked the Minister of Health whether, in view of the inconvenience and annoyance suffered by the public through certain ditches in the country becoming silted up and overgrown, causing a breeding place for mosquitoes and other insects, he will give instructions to all local authorities and owners of land containing such stagnant pools to be compelled under the Public Health Act to have these places cleaned out and sprayed with an adequate insecticide.—Mr. CHAMBERLAIN replied: I have no authority to give such instructions. Under Section 91 of the Public Health Act, 1875, any pool, ditch, &c., in such a state as to be a nuisance or injurious to health is to be deemed a nuisance liable to be dealt with under the Act. The question whether any particular pool is a nuisance is one of fact to be determined by the court in any proceedings instituted under the Section.

Model By-Laws for Hop-Picking Areas.

Mr. BRIANT asked the Minister of Health how many district councils had adopted the model by-laws issued early in 1926 for the better regulation of hop-picking areas.—Mr. CHAMBERLAIN replied: Eleven councils have made by-laws based on the new model.

Quarantine for Imported Dogs.

Lord APSLEY asked the Minister of Agriculture whether, seeing that the maximum period of incubation of any disease, including rabies, in dogs was two months, he would consider the reduction of the present period of six months' quarantine in certain establishments approved by his department of dogs taken from England, but brought back by their owners, on the ground that many of the latter could not, owing to financial circumstances, afford to pay the necessary charges for this period.—Mr. GUINNESS replied: My noble friend is in error as to the maximum incubation period of rabies, as dogs from abroad have developed rabies from three to five and a half months after they have arrived at quarantine stations in this country. I do not consider that inability to pay the necessary quarantine charges would justify me in reducing the period of quarantine and thereby adding very considerably to the risk of the introduction of such a terrible disease into this country.

Insanitary Slums in Glasgow.

Mr. ERNEST BROWN asked the Secretary of State for Scotland if his attention had been drawn to the Eighth Annual Report of the Scottish Board of Health, and, in particular, to Chapter 2, paragraph 16, as to the insanitary condition in Glasgow slums, and if any action had been taken on this report or, if not, if the Board of Health contemplated immediate action to deal with these conditions.—Sir JOHN GILMOUR replied: I am aware of the terms of the paragraph in question. As indicated therein it is a quotation from the report of the Commissioner appointed by the Scottish Board of Health to inquire into an improvement scheme submitted by the corporation of Glasgow under Part II. of the Housing (Scotland) Act, 1925. Details of the corporation's proposals for dealing with the areas to which the Commissioner's report refers will be found in paragraph 15 of the report. The improvement scheme has now been confirmed by the Board, and the local authority are in course of carrying out its provisions, which include the demolition and clearing away of the insanitary properties and the provision of new dwellings to rehouse the dispossessed tenants.

FRIDAY, JULY 1ST.

Ex-Service Men and Medical Treatment.

Mr. DAY asked the Minister of Pensions how many wounded men were still undergoing treatment as a result of the late war.—Major TRYON replied: The number of men suffering from wounds or injuries, as distinct from other classes of disability, who may be undergoing treatment are not separately recorded, but I may say that at the end of May 5000 officers and men were in receipt of surgical treatment of one kind or another.

MONDAY, JULY 4TH.

Colonial Scientific Research.

Captain CROOKSHANK asked the Secretary of State for the Colonies whether any action was being taken towards creating a single Colonial scientific and research service as recommended in the report submitted by Lord Lovat and his colleagues to the recent Colonial Office conference.—Mr. AMERY replied: As my hon. and gallant friend will recollect, the committee of the Colonial Office Conference, over which Lord Lovat presided, while recommending the ultimate creation of a single colonial research service, recognised that the natural method of growth of such a service was the organisation, in the first instance, of workers in the various fields of science into separate services. I have already appointed a committee in accordance with the recommendation referred to by my hon. and gallant friend to formulate practical proposals, for submission to Colonial Governments, to give effect to the resolution of the Colonial Office Conference, on the subject of a Colonial agricultural research service, and it is proposed that the recently appointed Colonial Medical Research Committee should, as one of its first tasks, consider the organisation of a Colonial medical research service. I may also say that steps are now being taken to set up another committee to inquire into the present condition of the Colonial veterinary services. This committee will no doubt consider the possibility of establishing a veterinary research service common to all the colonies protectorates, &c. As regards forestry, I propose to defer consideration of the question of constituting a Colonial forestry research service until after the meeting of the Empire Forestry Conference, to be held at Melbourne in 1928.

Illicit Importation of Drugs.

Sir ROBERT THOMAS asked the Secretary of State for the Home Department whether the illicit importation of drugs into this country had increased since the war; from what countries they were principally introduced; and whether there had been any recent arrests for this offence.—Sir W. JOYNSON-HICKS replied: No, Sir. While it is not possible to speak positively in a matter of this kind, all our experience goes to show that the illicit importation of dangerous drugs has diminished since the passing of the Dangerous Drugs Act of 1920. No arrest of any importance has been made this year. I shall be happy to send the hon. Member—as soon as it is available—a copy of the report made by His Majesty's Government to the League of Nations on the control of the drug traffic in respect of 1926, which contains a table giving particulars of all cases during the year in which seizures were made.

Indian Medical Service.

Sir RICHARD LUCE asked the Under Secretary of State for India how many European and how many Indian medical officers, respectively, had entered and retired from the

Indian Medical Service in each of the years 1923, 1924, 1925, 1926, and 1927; what was the total number of each category now serving; and what was the proportion of Europeans to Indians that was considered requisite for the satisfactory working of the service in the military and civil branches, respectively.—Earl WINTERTON replied: The table below shows the recruitment of, and casualties among, permanent officers of the Indian Medical Service during the years 1923–27.

Year.	Recruitment.		Casualties from all causes—i.e., retirements on pension, deaths, removals, and resignations.	
	European.	Indian.	European.	Indian.
1923	17	—	41	4
1924	21	—	17	1
1925	11	10	31	1
1926	12	3	29	3
1927 to date	12	2	16	1

According to the latest Army list there are now 489 British and 158 Indian officers holding permanent commissions in the Indian Medical Service. The ratio of approximately one Indian to two European officers has been accepted for both the civil and the military sides of the Indian Medical Service.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 25TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 259 (last week 219); scarlet fever, 1553; diphtheria, 725; enteric fever, 95; pneumonia, 913; puerperal fever, 42; puerperal pyrexia, 115; cerebro-spinal fever, 4; acute poliomyelitis, 6; acute polioencephalitis, 1; encephalitis lethargica, 33; dysentery, 2; ophthalmia neonatorum, 109. There were no cases of cholera, plague, or typhus fever notified during the week.

Cases of small-pox were notified from the counties of Derby 4 (Derby C.B.), Durham 126, Lancaster 16, Northampton 1 (Northampton C.B.), Northumberland 19, Stafford 7 (Burton-on-Trent), Yorks, West Riding 39, Glamorgan 8 (Cardiff 2, Merthyr Tydfil 1, Gelligaer 5), and Monmouth 39. None was returned from London, Kent, Middlesex, Nottingham, Southampton, North Riding of Yorkshire, or the City of York.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, (0) from enteric fever, 30 (1) from measles, 4 (0) from scarlet fever, 19 (8) from whooping-cough, 17 (4) from diphtheria, 39 (3) from diarrhœa and enteritis under two years, and 33 (3) from influenza. The figures in parentheses are those for London itself.

INDEX TO "THE LANCET," VOL. I., 1927.

THE Index and Title-page to Vol. I., 1927, which was completed with the issue of June 25th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

A CENTRAL CRIPPLES' HOSPITAL FOR EDINBURGH.—Considerable progress was reported at a recent meeting in connexion with the £75,000 scheme for a Central Cripples' Hospital for Edinburgh and the south-eastern area of Scotland. At least 3000 more beds are required in the Scottish hospitals which are burdened with long waiting-lists, but could the present scheme mature, the crippled child will be assisted elsewhere and thus relieve the pressure on hospital beds. Sir David Wallace pointed out that not only the need existed for early surgical treatment, but also facilities for continuity of treatment.

Medical News.

UNIVERSITY OF OXFORD: *Schorstein Research Fellowship.*—The Board of the Faculty of Medicine has elected Jean Orr-Ewing, M.A., B.M., Lady Margaret Hall, to the Schorstein Research Fellowship in Medical Science for two years from Oct. 1st, 1927. Miss Orr-Ewing has been engaged in pathological research in the University for several years past, and intends to continue her investigations in the Sir William Dunn School of Pathology.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At an extraordinary meeting of the College held on June 14th it was decided, in celebration of the Lister centenary, to confer the Honorary Fellowship of the College upon the Earl of Balfour; Sir John Rose Bradford, P.R.C.P. Lond., F.R.S.; Sir Hector Cameron; Mr. Neville Chamberlain, Minister of Health; Sir William Watson Cheyne; Sir David Ferrier, F.R.S.; Sir John Gilmour, Secretary for Scotland; Dr. Thorvald Madsen, Director of the Statens Seruminstitut at Copenhagen; and Dr. Arthur Logan Turner, P.R.C.S. Edin.

UNIVERSITY OF BIRMINGHAM.—At recent examinations the following have been successful:—

L.D.S.—C. T. Morgan, A. H. Bosworth, S. L. Barnacle, W. H. Brown, W. L. Eccleston, B. H. Johnson, R. E. Morgan, G. Simons, A. T. Wynne.

UNIVERSITY OF SHEFFIELD.—At the undermentioned examinations held recently in the Faculty of Medicine the following candidates were successful:—

M.D.—Harry N. Green.

Final M.B., Ch.B.—With Honours: Class II., William L. Rowe. Ordinary: Dorothy Brown, Bernard Graham, Donald H. Lockwood, Philip G. Preston, and William G. P. Wells.

UNIVERSITY OF DUBLIN: SCHOOL OF PHYSIC, TRINITY COLLEGE.—At recent examinations the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.—*Frederick G. Stewart, Nora A. Stack, John Beggs, Josephine M. Enright, Marie M. E. Lea-Wilson, Louis L. Griffiths, Everest S. Adderley, Eric F. St. J. Lyburn, Patrick O'Shea, Geoffrey B. Thrift, William A. Y. Knight, John Willoughby, Eric C. Hicks, and John T. M'Ginn.

Part II., Medicine.—*Terence J. Millin, Solomon Behr, Robert R. Woods, Thomas C. M. Corbet, Gilbert M. Smith, Paul M. Garry, Thomas J. O'Reilly, Joseph A. K. FitzGerald, Richard M. Moore, George M'Donald, Lenox R. S. MacFarlane, Ethel M. Weir, Isidore Isaacson, John K. Harper, William P. Culbertson, Arthur R. Gray, Claud E. G. Nunns, and Izaak le Roux.

Surgery.—*Terence J. Millin, Thomas C. M. Corbet, Wilfred F. Lane, Robert A. Q. O'Meara, Maurice F. N. Griffin, Robert S. F. Hennessey, Maximilian Gerber, Thomas J. O'Reilly, Norah W. Brown, Myer Hoffman, Robert D. Whiteacre, Patrick Brangan, Charles L. Day, Norman J. U. Mather, George Q. Chance, Donal B. O'Sullivan-Beare, Samuel R. Elmes, Shirley D. K. Roberts, Ralph W. T. H. Stewart, Cecil F. Cope, Desmond Blewitt, John O. Bennett, Samuel B. Dalrymple, Edward M. Gamble, Hubert C. Weir, Lenox R. S. MacFarlane, William P. Culbertson, Norah E. Fenton, James J. FitzGerald, and Joseph A. K. FitzGerald.

Midwifery.—*William J. E. Jessop, *Evan K. Malone, *Kenneth Watson, David M'M. Carson, Ernest du Plessis Meiring, John J. O'Dwyer, Denis S. P. Wilson, Robert D. Whiteacre, Leslie R. H. Keatinge, and Nathaniel Burstein.

FINAL DENTAL EXAMINATION.

Dental Surgery and Pathology; Dental Mechanics and Metallurgy; Orthodontics.—Andrew A. Gardner, Thomas J. L. Stafford, and Gertrude G. Hill.

* Passed on high marks.

UNIVERSITY OF DURHAM.—At a convocation held in Durham on June 28th Sir James Berry received the degree of D.C.L. Honoris Causa. He was presented by Mr. G. Grey Turner, who has been recently appointed to the Chair of Surgery.

Other recent appointments at the College of Medicine, Newcastle, are as follows:—Sir Thomas Oliver: Emeritus Professor of Medicine. Prof. H. Brunton Angus: Emeritus Professor of Surgery. Dr. Thomas Beattie: Professor of Medicine.

MINERS' CONVALESCENT HOME.—On June 28th the Prince of Wales formally opened the Lancashire and Cheshire Miners' Convalescent Home at Bispham, a northern suburb of Blackpool. The home was built with part of the proceeds of the Miners' Welfare Fund, and cost about £150,000.

UNIVERSITY OF GLASGOW.—The Harry Stewart Hutchison prize of £50 for writings embodying original research work in a branch of medical science relating to children has been awarded to Dr. Robert Cruickshank for an essay on the Intestinal Flora of Infants and Young Children in Health and Disease. The Macewen medal in surgery has been awarded to Dr. Marion W. Gray.—On July 1st the degree of M.D. was conferred on Thomas Walter Hill for a thesis on the Significance of Caloric Labyrinthine Stimulation in the Diagnosis, Prognosis, and Treatment of Certain Pathological Conditions.

SHANTUNG CHRISTIAN UNIVERSITY, TSINAN-FU, CHINA.—Dr. Harold Balme, who has been President of the University since 1921, has, for family reasons, resigned his position. Dr. Balme went to China as a medical missionary in 1906, and became professor of surgery at Shantung University in 1912. He has been chairman of the Council on Medical Education of the China Medical Missionary Association, and was first President of the China Association for Christian Higher Education. He was also vice-chairman of the National Christian Council of China, and the author of "China and Modern Medicine," and other books. His resignation was accepted by the British section of the Board of Governors with great regret.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—The annual general meeting of this society will be held at 11, Chandos-street, London, W., on Friday, July 15th, at 8.30 P.M., when Dr. D. Nabarro will read a paper on Some Problems Associated with the Transmission of Syphilis to the Second and Third Generation. A discussion will follow.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.—An American meeting of this society will be held at the house of the British Medical Association, Tavistock-square, on July 11th, at 3 P.M., when a discussion will take place on the possibility of closer coöperation between the society and fellow-workers on the American continent. Dr. Eugene L. Opie, of the Henry Phipps Institute, Philadelphia, will read a paper on Latent Tuberculosis and its Relation to Manifest Disease, and Dr. H. Longstreet Taylor, President of the National Association for the Prevention of Tuberculosis in America, will give a lantern demonstration on Sanatorium Treatment in Cold Climates.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.—The eighth annual general meeting of this society was held at 143, Harley-street, London, W., on June 28th, Sir Basil Peto, M.P., President, being in the chair. The following resolution was carried unanimously:—

"That this meeting desires to call the attention of the Minister of Health and the public to the facts:—

"(1) That recently a man was sentenced in Manchester to six weeks' imprisonment for selling printed information similar to that distributed by this Society.

"(2) That the man had sold similar printed information in other districts without prosecution and with the unofficial approval of medical officers of health and military commanding officers.

"(3) That the information supplied by this man was similar to that which is quite legally distributed by certain local authorities.

"(4) That the methods of prevention described were those which have been officially taught and successfully practised in the Navy, Army, and elsewhere.

"(5) That the above facts illustrate the present contradictory and deplorable legal position.

"(6) That in view of the prevalence of venereal disease and its disastrous results on national efficiency and the great cost of the present method of dealing with it only by curative and not preventative methods, as well as of the above facts the Society for the Prevention of Venereal Disease calls upon the Ministry of Health to amend the Venereal Disease Act, 1917, so as to give effect to the recommendation contained in Clause 14 of the Report of the Departmental Committee of Inquiry held under the chairmanship of Lord Trevethin in 1923,

"'That the law should be altered so as to permit properly qualified chemists to sell *ad hoc* disinfectants provided such disinfectants are sold in a form approved and with instructions for use approved by some competent authority.'"

Dr. J. H. Sequeira stated his belief that there was at the present time an increase in venereal disease, due, in his opinion, to the fact that a post-war generation had arisen which had not received instruction in disinfection. Sir James Crichton-Browne said that Great Britain, although maintaining her position in preventive medicine generally, was falling behind the other nations of the world in regard to the prevention of venereal disease. He pointed out the remarkable position that the hon. secretary of the society was giving lectures to prisoners at one of the large prisons at the invitation of the prison authorities and imparting scientific information, while one of his audience might possibly be undergoing sentence in that very prison for imparting similar information in leaflet form to the public outside.

THE King has confirmed the appointment of Dr. N. L. Clarke as a nominated unofficial member of the Legislative Council of the Straits Settlements.

NEW PATHOLOGICAL LABORATORY AND RESEARCH INSTITUTE.—On Tuesday, July 19th, at 3 P.M., Mr. Neville Chamberlain, Minister of Health, will open the new pathological laboratory and research institute which is a gift to the City of London Hospital for Diseases of the Heart and Lungs, Victoria-park, E. 2, from the Prudential Assurance Company. The ceremony will be succeeded by a garden party to meet the Lady Maud Carnegie, President of the Ladies' Association of the hospital.

BRITISH PATHOLOGISTS' ASSOCIATION.—The summer meeting will be held in London on July 15th, beginning at 10 A.M., at the National Hospital, Queen-square, when the following papers will be given:—Dr. J. G. Greenfield: The Clinical Pathology of the Cerebro-Spinal Fluid; Dr. F. B. Smith: Significance of the Relationship of Total Chlorides and Free Acid in Gastric Contents; Dr. A. Renshaw: The Economics of Laboratory Administration; Dr. S. C. Dyke: The Determination of Compatibility in Blood Donors; Dr. E. Wordley: Observations on Fibro-Sarcomata of Bone with Illustrative Specimens; Dr. A. D. Fraser: Endometriomata with Illustrative Specimens. In the afternoon demonstrations at the Pathological Laboratory, National Hospital, will be given by Dr. J. G. Greenfield, Mr. Anderson, and Dr. G. Hadfield; and at the Hospital for Sick Children, Great Ormond-street by Dr. D. Nabarro, Dr. D. McClean, Dr. W. W. Payne, and Dr. H. Archer. At 5 P.M. a general meeting will be held at the B.M.A. House, Tavistock-square, Dr. C. Powell White presiding, when a discussion on Progress and Future Policy will be opened by the Chairman and Dr. J. G. Greenfield. At 6.15 P.M. at the same place Sir Thomas Horder will give an address on the Need of Standardisation in Clinical Pathology.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS.—The second meeting of this newly formed society was held in Manchester on June 24th and 25th, under the Presidency of Sir Charles Ballance. The recently elected associate members were admitted by the President. In addition to a full attendance of members and associates Prof. Harvey Cushing was present and took part in the discussions. On the first morning Mr. Geoffrey Jefferson operated upon a case of neuralgia, dividing the sensory root of the Gasserian ganglion, and then exhibited a number of cases as a basis of general discussion. In the afternoon Prof. Shaw Dunn made some observations on a series of intracranial aneurysms, pointing out how commonly they were the cause of fatal intradural (subarachnoid) hæmorrhage. But he insisted that unless they were carefully searched for and the clot faithfully removed they were very apt to be overlooked. Mr. Wilfred Trotter followed by giving his reflections on the surgical treatment of some of the larger intracranial aneurysms, which were, he said, not uncommon and were being recognised clinically rather more often than formerly. Mr. Percy Sargent read a paper on two cases of angioma of the pia arachnoid cerebri, giving an account of the clinical findings in his cases, the operative appearances, and the after-histories. He discussed the difficult question of correct pathological grouping, and Prof. Dunn described the histology of a case he had met with. Dr. N. D. Royle gave an address, based on a series of cinematograph films, on the effects of sympathetic ramisectomy in cases of spastic paralysis. In many of these a striking improvement was apparent, but it was suggested that similar results could be obtained by older-established orthopædic measures. Dr. Royle thought that much more rapid improvement took place after ramisectomy, and declared that unless vascular changes were noted in the limb after operation it could not be held that a proper sympathectomy had been performed. On the morning of June 25th, after Dr. Stewart had described briefly his work on the innervation of the teeth, Dr. Arthur Hall gave an exposition of the reflexes controlling posture. He defined clearly the meaning of Magnus's nomenclature and illustrated several of the tonic reflexes by means of cinematograph films, models, and diagrams. Mr. Cecil Calvert gave an account of two cases of cerebral tumour attempting to account for the localised pain, of which they had complained by reference to the innervation of the dura. Mr. Morris showed the anatomy of the Haertel method of injecting the Gasserian ganglion, and of a slight but important alteration in the site and traject of puncture. He believed that the injection material tended to run back into the root of the ganglion, and gave permanently satisfactory results. In discussion members mentioned the serious results which sometimes followed these injections but Mr. Morris stated that he had not seen them, though transient palsy of the abducens sometimes occurred. Keratitis was rarely severe.

PRESCRIBING BY INSURANCE PRACTITIONERS.—At an emergency meeting of the executive committee of the Kent Local Medical and Panel Committees, held on June 29th at Canterbury, the proposed new agreement between the Ministry of Health and chemists as to prescribing by insurance practitioners was discussed. A resolution was passed to the effect: That the proposed arrangement which would make it possible and financially profitable for chemists to limit the quality and quantity of medicines prescribed for insured persons is contrary to public policy and must be resisted by every possible means.

MEMORIAL TO A MEDICAL MAN.—On June 29th the town of Blackpool honoured the memory of William Henry Cocker, L.S.A., M.R.C.S. Eng., J.P., the first Mayor and Honorary Freeman of the borough, when a memorial four-sided clock tower 85 feet in height was unveiled in the Stanley Park. Dr. Cocker was born in 1836 and died in 1911 at the age of 74. He was one of the pioneers of Blackpool who did much to found and establish the town as one of the most prominent seaside health resorts in the kingdom. He rendered eminent services to the municipality, was elected mayor on six occasions, and was a member of the town council for 36 years.

INSANITARY SCHOOL BUILDINGS IN IRELAND.—At a public meeting of national school teachers held at Naas, County Kildare, last week, attention was drawn by more than one speaker to the insanitary condition of many of the school buildings, and its ill-effect on the health of the pupils. One teacher stated that much of the ill-health of after years had its origin in the hovels which passed for school-rooms in so many parts of the country.

Many of those rooms, he said, were structurally unhygienic and dangerously insanitary. They were veritable death-traps. Many of them were built 70 or 80 years ago during the experimental stage of Irish primary education, when the science of hygiene was unknown in Ireland, and when the provision of a roof and walls was considered the acme of comfort. Bad as were the structural defects of some of the schools, their danger to health was insignificant compared with the situation and condition of the out-offices which violated not only the laws of health, but even the laws of common decency. Medical inspection of school-children, he held, would inevitably go far to remedy the existing state of affairs.

It is satisfactory to find, our correspondent remarks, that the teachers throughout the country are the most active in pressing for medical inspection of school-children to be carried out.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, July 11th, to SATURDAY, July 16th.—FELLOWSHIP OF MEDICINE DEMONSTRATIONS. Tues., 2.30 P.M., at In-Patient Department, St. John's Hospital for Diseases of the Skin, Uxbridge-road, W. Demonstration by Dr. A. C. Roxburgh. Fri., 10 A.M., at Central London Throat, Nose, and Ear Hospital, demonstration by Mr. Archer Ryland. Those desirous of being present at this demonstration please notify hospital—Museum 1539. Fri., at 5 P.M., at Royal Westminster Ophthalmic Hospital, lecture, Epiphora, by Mr. G. Viner. These demonstrations are free to all members of the medical profession.—NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's Hospital, Tottenham, N.—Vacation Course—all day, 10.30 A.M. to 5.30 P.M. 4.30 P.M., lectures free to members of the Fellowship of Medicine.—ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM, City-road, E.C. Special course in Proctology for one week.—PARK HOSPITAL, Hither Green, S.E. Course in Infectious Fevers. Wed., 2.30 P.M., and Sat., at 11 A.M.—WEST-END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Lecture-demonstrations at 5 P.M., daily throughout the month. Further information from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 11th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M., to 5 P.M. Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, July 14th.—4 P.M., Dr. Nabarro: Vaccine Therapy.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, July 11th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Donald Armour: Operations.

TUESDAY.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients. 3 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology, 2 P.M., Mr. Gibb: Eye Department.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 3 P.M., Sir Henry Simson: Gynæcological Ward.

FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Operations. Mr. Vlasto: Throat, Nose and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy and Ward Visit. 10 A.M., Dr. Owen: Medical Diseases of Children.

Operations, Medical, Surgical, and Special Out-patients, daily, 10 A.M. to 5 P.M.; Saturdays, 10 A.M. to 1 P.M.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, July 12th.—3.15 P.M., Mr. Kenneth M. Walker: Recent Advances in the Diagnosis and Treatment of Genito-Urinary Disease.

Appointments.

THOMPSON, A. G. G., M.D. Camb., D.P.H., has been appointed, Medical Officer for Lambeth.

London School of Dermatology, St. John's Hospital for Diseases of the Skin: DRAKE, J. A., M.D. Lond., and O'DONOVAN, W. J., M.D. Lond., Lecturers.

Manchester Royal Infirmary: LINFORD, H., M.B. Manch., Resident Junior Assistant House Surgeon (Central Branch); GRAY, E. D., M.B. Lond., Junior Assistant Medical Officer, Radiological Department; LEIGHT, A. T., M.B. Manch., Anæsthetist (Central Branch); SMIRK, F. H., M.D. Manch., Medical Registrar; LAMBERT, V. F., F.R.C.S. Edin., Assistant Surgical Officer Aural Department; ASHCROFT, G. V., M.D. Manch., M.R.C.P. Lond., D.P.H., Assistant Medical Officer.

Certifying Surgeons under the Factory and Workshop Acts: CAMERON, I. M., M.B., Ch.B. Edin. (Tarbert District of the County of Argyll); WIGFIELD, F. P., M.B., B.S. Durh. (Buntingford District of the County of Hertford.)

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—Asst. H.S. £130.

Birmingham and Midland Eye Hospital, Church-street.—Physico-Therapist to Ultra-Violet Ray Dept. £100.

Bodmin, Cornwall County Mental Hospital.—Asst. M.O. £350.

Bradford, Royal Eye and Ear Hospital.—Res. H.S. £120.

Brighton, Royal Alexandra Hosp. for Sick Children.—H.P. £100.

Bristol Union.—Demonstrations in Pathology. £400.

Cardiff City Mental Hospital, Whitchurch, near Cardiff.—Second Asst. M.O. £350.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.

City of London Hospital for Diseases of the Heart, &c., Victoria Park, E.—H.P. At rate of £100.

Coventry and Warwickshire Hospital.—Hon. Asst. Surg.

Croydon County Borough.—Asst. M.O.H. and Asst. School M.O. £600.

Doncaster County Borough.—Asst. M.O.H. and Tub. O. £600.

Edinburgh University.—Chair of Medicine.

Evelina Hospital for Children, S.E.—Masseuse. £160. H.S. £120.

General Lying-in Hospital, York-road, Lambeth, S.E.—Registrar.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. £50 for six months.

Huddersfield Royal Infirmary.—Jun. H.S. £150.

Ilford Borough.—Chief Asst. M.O.H. £700.

Indian Medical Service.—Appointments.

Kensington Royal Borough Tuberculosis Dispensary.—Honorarium 35 guineas.

Kent Education Committee.—School M.O. £600.

Leeds City Sanatorium, Gateforth.—Res. M.O. £400.

Leeds General Infirmary.—Hon. Phys.

Manchester, Ancoats Hospital.—Pathological Registrar. At rate of £100. H.P. At rate of £100.

Manchester City.—Asst. Tuberculosis Officer. £650.

Manchester, St. Mary's Hospitals.—Two H.S.'s. Each at rate of £50.

Margate, Royal Sea Bathing Hospital.—Two H.S. At rate of £200.

Metropolitan Asylums Board.—Second Asst. M.O. £500. Jun. Asst. M.O. £500.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Hon. Asst. Gynæcologist. Cas. O. £150. H.S. £125.

National Association for the Prevention of Tuberculosis.—Asst. Medical Commissioner. £700.

New Delhi, India, Lady Hardinge Medical College.—Clin. Pathologist. Rs.450 per mensem.

Port Talbot, Borough of.—M.O.H. and Sch. M.O. £800.

Royal Army Medical Corps.—Commissions.

Royal Free Hospital, Gray's Inn-road, W.C.—Hon. Anæsthetist. Also Cas. O. £150.
Royal Northern Hospital, Holloway, N.—Surg. to Ear, Nose, and Throat Dept. Also P.
Royal Waterloo Hospital for Children and Women.—Hon. Radiologist. Hon. Gynæcologist.
Samaritan Free Hospital for Women.—Hon. Surg.
Sheffield Royal Hospital.—Resident Anæsthetist. Res. Ophth. H.S. £80 each.
Sheffield Royal Infirmary.—Ophth. H.S. At rate of £80. Also Hon. Asst. Ophth. S.
Sunderland County Borough.—Asst. M.O. for Maternity and Child Welfare. £600.
Swansea County Borough.—Asst. M.O. £600.
West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Reg.
West London Hospital, Hammersmith-road, W.—Res. Asst. S. £200.
Westminster Hospital.—Surg. Registrar. £150. Medical Registrar. £150.
Willesden General Hospital, Harlesden-road, N.W.—Phys. in Charge of Dept. for Dis. of Skin. Also H.S. At rate of £100.
Wolverhampton and Staffs Hospital.—H.S. At rate of £150. Also Hon. Surg.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Market Rasen (Lincolnshire). Bognor (Sussex); and at Aylesbury (Buckinghamshire).

Births, Marriages, and Deaths.

BIRTHS.

BESWICK.—On June 26th, at Goldsytch House, Mill Hill, N.W., the wife of Wilfrid Beswick, M.D., of a son.
DUCKWORTH.—On July 2nd, at South Parade, W., the wife of J. E. H. Duckworth, M.C., L.D.S. R.C.S., Eng., of a son.
GERARD-PEARSE.—On June 29th, at Somerset House, Weymouth, the wife of John Gerard-Pearse, F.R.C.S., of a son.
HUME.—On July 2nd, at 41, Southway, N.W. 11, the wife of J. Basil Hume, M.S., F.R.C.S., of a daughter.
MOODY.—On July 1st, at Bournemouth, the wife of Dr. A. J. Moody, of a daughter.

MARRIAGES.

CROOK—WILLMORE.—On June 27th, at St. Joseph's Church, Nympsfield, Glos., Bertram Austin Crook, M.B., Ch.B., M.R.C.S., L.R.C.P., of Paulton, Somerset, to Kathleen Marjorie Willmore, M.B., Ch.B., of Wotton-under-Edge.
GIBSON—ELLERTON.—On June 28th, at Holy Trinity, Sloane-street, Paul Currey Gibson, M.D., M.R.C.P., to Margaret, daughter of the Rev. F. G. Ellerton, Vicar of Tardebigge, and of Mrs. Ellerton.

DEATHS.

BRYAN.—On June 27th, at Fairfax-road, Chiswick, Edward Bryan, M.R.C.S., L.R.C.P., in his 85th year.
DAWSON.—On June 27th, at Queen-street, Edinburgh, James Walker Dawson, M.D., D.Sc., F.R.C.P.E. and F.R.C.S.E., aged 57.
DREAPER.—On June 28th, at the Royal Naval Hospital, Haslar, Gosport, Surgeon Rear-Admiral (retd.) George Albert Dreaper, C.B., K.H.S.
HIGGINSON.—On June 26th, at a nursing home, after an operation, Charles Gaskell Higginson, M.D., M.A., of Portland-road, Edgbaston, aged 68.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

MEMORIAL TO DAME LOUISA ALDRICH-BLAKE.—On July 5th Sir William Beveridge, Vice-Chancellor of the University of London, unveiled a memorial to Dame Louisa Aldrich-Blake in Tavistock-square-gardens. The memorial was designed by Sir Edwin Lutyens. On either side are bronze busts by Mr. Arthur Walker, based on the portrait of Dame Louisa Aldrich-Blake by Sir William Orpen. Dame Mary Scharlieb presided at the ceremony and called in turn upon those who had been closely associated with Dame Louisa Aldrich-Blake to add their tribute. Sir William Beveridge recalled her as a skilled surgeon and administrator with high academic ideals. Lord Riddell, her biographer, who as President of the Royal Free Hospital was chairman of the Memorial Committee, said the memorial would perpetuate the memory of a great lady who had conferred great benefits on that district. Miss Elizabeth Bolton, chairman of the medical board of the Elizabeth Garrett Anderson Hospital, said that Dame Louisa Aldrich-Blake had served the hospital for 30 years and had done her chosen work with great distinction. Finally Lady Barrett, Dean of the London School of Medicine for Women, paid a tribute to the work of her predecessor as dean of the school. The Benediction was pronounced by the Rev. F. H. Aldrich-Blake. Besides the monument the memorial includes the endowment of a travelling scholarship open to all medical women graduates in the United Kingdom and replicas for the Royal Free and the Elizabeth Garrett Anderson Hospitals of the portrait by Sir William Orpen, which is the property of the London (R.F.H.) School of Medicine for Women.

Notes, Comments, and Abstracts.

THE LONDON HOSPITAL.

DISTRIBUTION OF PRIZES BY LORD EUSTACE PERCY.

THE prize distribution took place in the Library of the Medical College on June 29th, Lieut.-Colonel W. Marlborough Pryor, Chairman of the College Board, presiding.

Dr. W. Wright, the Dean of the Medical College, enumerated some of the distinctions gained by past and present students during the year, recorded changes in the personnel of the honorary staff, and chronicled the death of Dr. Francis Warner, Mr. Warren Tay, and Mr. T. A. M. Ross. He spoke of the benefactions given to the hospital and college by the late Lord Bearsted and by Mr. Bernhard Baron, who had this year presented a further £25,000 towards the endowment of the pathological institute, which would in future be known as the Bernhard Baron Pathological Institute. The new residents' hostel on the north side of the out-patient department was now completed. This hostel was for the accommodation of the junior staff of the hospital, and in no way met, but rather emphasised, the need of an adequate students' hostel.

Lord Eustace Percy, M.P., who distributed the prizes, spoke of his responsibilities in connexion with the large medical staff employed by the Board of Education over which he presided. He was responsible to Parliament, if to nobody else, for the work of some 1100 medical officers, not to mention 1300 specialist officers, and between 4000 and 5000 nurses in the schools. He was the more alarmed for his responsibilities when he considered how rapidly this school medical service was growing in certain directions. In the last two years there had been an increase of nearly 20 per cent. in the school clinics in operation in England and Wales—some 1400 now existed. There had been in the same period an increase of over 20 per cent. in the number of hospitals with whom local authorities had arrangements relating to the treatment and care of school-children. The number of local authorities having schemes of orthopædic ascertainment and treatment in their areas had increased by something like 240 per cent. in a period of two years. He might well feel that he represented one branch of those public activities which would depend mainly, in fact wholly, upon doctors for their support in the future. He thought perhaps that this care of children represented the most important part of our public work, for the years of life between 5 and 14 and sometimes below 5, were perhaps years in which most could be done in the way of preventing disease and disability and of insuring health throughout after-life. This task of improving the general health of children of those ages, remedying curable defects, was perhaps the greatest public medical activity being undertaken at the present moment.

Education and Craftsmanship.

He suggested two reflections, connected with the two capacities in which he appeared before them. One was, on the educational side, the reflection of the privileges which they enjoyed as members of a skilled profession with definite qualifications attested by recognised academic authorities. A comparatively few people enjoyed privileges of that kind. The medical profession was often ignorantly, and even maliciously, publicly referred as a trade-union; he was not sure that it was a title which the medical profession need repudiate. For the skilled professions originated historically in the same way as the industrial crafts. They originated from the same guild system, and, in the Middle Ages at any rate, the medical profession was no less and no more a guild than any industrial craft. But whereas throughout succeeding centuries since then the skilled professions, and above all the medical profession, had coöperated steadily with the universities and schools of this country, and indeed in a measure imposed their requirements for education on the universities and schools of this country, and had thus become an integral part and a controlling factor in our national system of education, the industrial crafts had not exercised the same influence. In the course of all those developments which were customarily lumped together under the name of the industrial revolution the industrial crafts which used to confer upon their members a status no less distinct and no less eminent than that of the skilled professions, had in a way sunk back, so that even the skilled industrial worker with a good secondary school education did not enter his working life with any such definite qualifications behind him as did the member of the skilled professions, and did not feel that he has the same status in the community that the members of the skilled professions held. And perhaps to this might be attributed a very large part of what was known as social and industrial unrest. Now medical men were in some

sort the mediators between the richer and the poorer classes of this country. They had in that respect a great function to perform; the example set by the system of medical education might be of the very greatest service in the future in building up a desire and a demand for more or less similar ideals of education in industry. The medical profession has been able to mould and to a certain extent control university and school education in the past, because it had not fallen into that fatal error of drawing a hard-and-fast line between a liberal and a vocational education.

The present distinction between vocational and general education and technical education would tend to disappear as industries and occupations developed educational requirements for themselves. Lord Eustace Percy suggested for their consideration the standard and type of education required by those who worked in what used to be called crafts and were now called for the most part the industries of the country. In short, he put it to them that those citizens who were discontented were discontended mainly because they felt that they lacked any definite status in the community; they had been prepared by their education with no definite qualification, and their membership of trade and industrial systems depended upon no educational qualifications.

A Discriminating Judgment.

The second reflection he wished to suggest was that professional skill was useless unless it was guided by that incommunicable gift of judgment which could never be taught, but which it was the main aim of education to enable men gradually and insensibly to acquire. He wondered how much of a doctor's actual working time was spent in scientific diagnosis and how much was occupied in mere human advice, not only to his patient, but to half the members of his patient's family. Our medical education, as all types and classes of education in this country, would in the long run be judged perhaps more than anything else by its power to communicate, to encourage, that exercise of human judgment on which we as a nation have prided ourselves in the past more than upon any other quality. As an example from the School Medical Service he took the mental defective problem among school-children in this country. At what point was it desirable to segregate a child who was not mentally up to the mark and was something more than merely a case of backward development? At what point was it desirable to segregate such a child in a special school? To what extent was it desirable to put that child cheek by jowl in that special school with varying types and grades of mental defect? At what age did association with lower grade defectives become harmful to the higher grade defective child? All these problems are problems which required for their solution, indeed a certain amount, a great deal, of high skill and deep scientific knowledge, but which at the same time required more than anything else perhaps the saving gift of common sense and the exercise of a discriminating judgment, and, above all, a sympathetic knowledge of human nature.

Lord Knutsford proposed, and Dr. Robert Hutchison seconded, a vote of thanks to Lord Eustace Percy.

Dr. Hutchison expressed regret that no prizes had been distributed to the teachers. He suggested for future occasions that there might be a prize for the teacher who had given the least boring course of lectures, for the man who had attended his wards with the least degree of unpunctuality, and possibly for the assistant surgeon, who had made fewest bad jokes in the out-patient department. These were all negative virtues, the teacher's positive virtues being beyond any hope of possible reward. If physicians were fortunate enough to win a prize the most appropriate form would be a cheque; for surgeons he thought possibly a book. He concluded a witty speech on a more serious note. There could be no more important work, he said, than to train the rising generation of doctors. The teachers at the London Hospital were vain enough to think that they engage in that work with a considerable degree of success, and that the men turned out—not merely the distinguished students, but the ordinary ones—when they left the College were as fitted for the responsibilities of the profession as the products of any medical school anywhere. They had to face certain difficulties, geographical, financial, and others, which were not felt in the same degree by all other schools, and it was therefore a great encouragement to them to feel that they had the sympathy of the head of the educational department of the country.

NEW CLINICAL THEATRE.

The Bearsted Memorial Clinical Theatre at the London Hospital was opened by Lord Bearsted on June 29th. Lord Knutsford, chairman of the hospital, presided, and recalled the many benefactions given to the hospital by the late Lord Bearsted. To him they owed the whole of the building of the new clinical theatre and a lectureship in connexion with it. Lord Bearsted had only attached one condition to his gift: that it should be open to all classes, all religions, all sects, without distinction. That had always been the tradition of the hospital.

Dr. Robert Hutchison said that the hospital had badly needed a clinical theatre. The one formerly in use was ill-adapted to its purpose, for it was noisy and the teachers had to compete with the noises of the road, often to disadvantage; when that theatre was done away with for a time none at all was available. A modern teaching hospital without a clinical theatre was an anomaly, for clinical teaching was the backbone of all medical instruction. At the London Hospital they had had in the past many distinguished clinical teachers. Men like Jonathan Hutchinson, Hughlings Jackson, Andrew Clark, Frederick Treves, and other great teachers did their work for the most part actually by the bedside, but with the development of modern medicine and teaching it had become a necessity to be able to demonstrate cases, particularly of a rarer type, to a large number of students simultaneously and to illustrate lectures by means of the lantern and epidiascope and other mechanical aids; for this more advanced type of clinical teaching a clinical theatre was a necessity.

Lord Bearsted spoke of his father's desire to show his interest in the hospital in a practical way during his own lifetime. He had felt the cure of disease must depend on knowledge; that the real reason and origin of disease must be found, rather than the palliative or curative effects when the disease has taken hold; and it was for that purpose that this theatre has been erected. In the medical profession there was no such thing as copyright. The medical profession placed its knowledge at the service of all, and that this knowledge should be increased in every way was the desire and the aim of everyone. He hoped that this theatre might prove some small addition to the manifold facilities for gaining knowledge which the hospital afforded.

CHEMISTRY IN THE PROGRESS OF MEDICINE.

IN his presidential address before the Society of Chemical Industry at Edinburgh on July 5th Mr. Francis H. Carr, C.B.E., took as his subject the place of chemistry in the progress of medicine. Pure and applied chemistry are, he said, equally necessary for advancement; progress may best be secured by coöperation in research between academic laboratories, research institutions, and industrial establishments. The chief underlying principle of medical treatment to-day consists in helping the body to produce its own curative agents. Most of the drugs employed in medicine do not cure directly, but by placing the body in a favourable position for exerting fully its own defensive mechanism. On the other hand, a few of the older drugs, such as cinchona and ipecacuanha, do act as direct curative agents. To the mode of action of such natural drugs and the synthetic chemotherapeutic substances which now find a place in medical treatment the lecturer directed particular attention.

Our knowledge of the physiology and biochemistry of living processes is, he said, not yet extensive enough for us to produce a reasoned plan on which to search for chemotherapeutic agents. The chemistry of insulin, of the principles of the pituitary and parathyroid glands, and of the ovarian hormone is still unknown, and although we know the chemical constitution of adrenalin, thyroxine, and histamine and can prepare these compounds synthetically, yet we are not certain as to the methods of their release from the glands which contain them, nor even whether they can exert their action without first being built within the body into more complex molecules. Of the real chemical nature of the bacterial antibodies we know nothing. In many diseases, especially those due to protozoal or amœboid parasites, antibodies do not appear to be formed. Hence chemotherapeutic agents are more than ever necessary, but we can obtain no clue to the type of compound required from our present knowledge of the antibodies and antitoxins.

After referring to the work of Ehrlich, Dale, Voegtlin, Fourneau, Kolle, and others, Mr. Carr concluded: It may not be altogether an accident that more effective therapeutic agencies have been discovered for protozoal diseases than for bacterial; the experimental work has been easier to carry out on animals and less reliance has been placed on purely in vitro experiments. The fact that a suitable animal test may lead to the discovery of a useful therapeutic substance is shown by the recent appearance of plasmochin, a quinoline derivative allied to quinine and most effective in the destruction of the crescent forms of the malarial parasite. The test animal used in this particular instance is the canary, infected with the parasite of avian malaria.

Future advance in chemotherapy lies in the direction of biochemistry and more effective contact between workers in chemistry, bacteriology, physiology, and clinical medicine. Less reliance must be placed on purely in vitro experiments and much more on adequate animal tests followed by extensive clinical trials.

MOTOR ACCIDENTS AND HOSPITALS.

IT is not surprising that the attention of the members of the British Hospitals Association, who met in conference recently at Norwich, should have been engaged the whole of the first afternoon in discussing the present unsatisfactory position of the voluntary hospital with regard to services rendered to the victims of motor accidents. The matter as regarded actuarily was ably and at times humorously dealt with by one of the vice-presidents of the Council of the Insurance Institute of London. He accounted for the vast number of accidents, which occur daily on the roads and streets, by the growth of motor traffic which has been so rapid that pedestrians have not accustomed themselves to the changed method of transport. The National Safety First Association is doing much to educate the public, and Mr. Jenkins pointed out that the very fact of the Association undertaking such work was a proof that it was recognised the motorist was not alone to blame for the many lamentable disasters which occur. Sir Arthur Stanley, at the dinner given in the evening to the delegates, asserted, as a good sportsman, that "if you have to be run over at all it is more pleasant to be run over by a motor-car than by an old four-wheeler, because in such a matter it is all to the motorist's credit that he can do the thing quickly!" Be this as it may—and after all it is a matter of opinion—in most hospitals, situated in or near a busy thoroughfare or an arterial road, 75 per cent. of the beds in the accident or surgical wards are frequently occupied by the victims of a motor smash. This state of affairs reacts badly on the voluntary hospitals in two directions; the waiting-lists of the institution, already in many cases terribly lengthy, are increased, and the hospital exchequer is ruthlessly depleted. As matters stand at present there is nothing but a feeling of gratitude or moral rectitude to ensure that a man or woman even attempts to pay for his keep and treatment in hospital, not to mention the skill of surgeons and nurses. From reports received these qualities seem often strangely deficient in the motorist and his victims, and no legal claim can be made by a voluntary hospital. The insurance expert is of opinion that a right given to a hospital to attach any portion of the insurance money would result in enhanced hospital charges as well as increased insurance premiums. The remedies at present put forward appear to be four. First, to quicken the moral sense of the casualty patient, so that he may pay more willingly—surely rather a forlorn hope. Secondly, that a special 10*s.* should be added to the motorist's insurance premium to enable him to settle the hospital claim. Thirdly, to enable the patient to pay off his indebtedness after recovery by a system of instalment contributions till the whole is discharged. (As it has been pointed out the motorist frequently buys his car on the instalment system, why not pay for his injuries in the same way?) Lastly, a suggestion was made in the *Times* by Dr. Henry J. Wells, in the issue of June 22nd, to the effect that motorists should subscribe to a fund designed to meet the heavy expenses to which hospitals are put by motoring accidents, and that the trustees of King Edward's Hospital Fund (or some such body) should agree to allocate, on a basis of the number of motoring accidents attended to, the sum placed at their disposal. We understand that the hon. secretaries of the Fund are considering this suggestion.

MUSTINESS IN EGGS.

THE "musty" egg has long figured as one of the minor trials of domestic life. In the past it has been regarded as falling in the same category as wet weather, thunderbolts, cats in the garden and other acts of God, and of the King's enemies as something inevitable, uncontrolled and fore-ordained. The light of science has now, however, been turned upon the musty egg and the cause of its fall from grace is apparent. Mr. A. W. Turner,[1] working in the Veterinary Research Institute of the University of Melbourne, has shown that the peculiarities of the musty egg are due to the working of a small Gram-negative bacillus which he aptly and with a fine ear for *le mot juste* proposes to call the *Achromobacter perolens*. This bacillus grows better at room than at body temperature, from which Mr. Turner deduces that musty eggs are not born in sin but acquire mustiness as a result of contact with the world. Experiments in which cultures of the *Achromobacter perolens* were rubbed upon eggs which had been thoroughly scrubbed and those which had received no such treatment demonstrated quite clearly that although the organism was able to pass through the shells of both, it did so with much greater ease in the case of the scrubbed eggs. From this Mr. Turner deduces a protective power imminent in the "bloom" or natural waxy coating of the egg-shell. This is a piece of research which should be of interest to those housewives who religiously scrub all eggs before placing them in water-glass.

[1] Achromobacter Perolens, the Cause of "Mustiness" in Eggs, by A. W. Turner, Australian Jour. of Experim. Biology and Medical Science, vol. iv., Part 1, 1927.

VACCINE TREATMENT OF ACUTE RHEUMATISM.

SOME experiences in the treatment of acute joint rheumatism in children with gonococcus vaccine have recently been described by E. Faerber and R. Kaplan.[1] The method of treatment followed was that of Brunthaler, who was the first to introduce treatment with vaccines of this organism, on the ground of its possible relation to the "rheumatic diplococcus." The vaccine employed (arthigon) contained 100,000,000 organisms per c.cm. in 40 per cent. urotropin solution. It was given intramuscularly at intervals of 2 to 3 days, the dose being 0·5 c.cm., increasing to 2·5 c.cm., and 5, 10, or 15 injections being given in all. Febrile reactions were slight and irregular and could not be relied on to indicate the length of treatment required. The result of treatment of 12 cases is reported, all the patients having suffered from rheumatism of joints at the time of admission. The series is short as articular rheumatism is not common and other cases were excluded as being insufficiently controlled. The observations covered periods of six months to four years. None of the cases had been treated with salicylates. Seven cases are reported to have remained free from valvular disease. Of five cases reported to have lesions on admission three have apparently recovered. Whilst claiming no certainty in the results Faerber and Kaplan strongly recommend further trial.

A SUPPLEMENT TO THE SANITARY TOWEL.

To the Editor of THE LANCET.

SIR,—An appliance has recently been brought to my notice which, I am convinced, fulfils a long-felt want. I have asked several of my patients to try it, and they all speak of it in terms of the highest praise. Briefly, it affords a complete protection for the inner aspect of a woman's thighs when wearing a vulval pad. It consists of two thin pieces of celluloid which fasten snugly round each thigh by means of an adjustable elastic garter, the adjustment ensuring an instant fit for either a stout or thin patient. A second elastic strap running up the outer side of the leg at right angles to the former is secured to the corset, keeping the whole thing securely in place. On either side of the celluloid is a soft, thin, absorbent gauze pad, the outer one to prevent the celluloid from touching the skin of the thigh, the inner, being in contact with the pad or towel, absorbs any blood or discharge. Each of these gauze pads can be detached instantly and thrown away when soiled, its place being taken by a new "refill." The celluloid can, if necessary, be cleaned with soap and water. Their combined weight, with straps and all, is under 3 ounces, and owing to their flexibility they conform to any movement, and when in position, I am assured, their presence cannot be felt. The chafing and irritation caused to many women by the prolonged use of a sanitary towel is very great, but this appliance not only prevents any discharge from reaching the skin but also prevents the towel itself from coming in contact with the skin. I believe a number of the large chemists are now stocking this article, but it can readily be obtained from the firm who is introducing it: the Queenett Co., 134, Cheapside, E.C.

I am, Sir, yours faithfully,

Harley-street, W. G. MURRAY HEIRON.

*** The appliance to which Dr. Heiron refers was submitted to us for inspection. It appears to fulfil the claim made for it by the manufacturers, and may well prove useful to women who suffer from profuse menstrual or other vaginal discharge.—ED. L.

CURRENT OFFICIAL STATISTICS.

WE have received from H.M. Stationery Office Vol. I of the Guide to Current Official Statistics, covering the year 1926 and part of 1927 in certain selected publications. The object of the guide is to direct the inquirer to all current official publications that contain statistics bearing on the subject in which he is interested, and more especially to inform him of the nature of the statistics he will find in the volumes to which he is referred. We have already commented on this useful book for anyone who desires, for instance, to look up such subjects as hospitals, infantile mortality, midwifery, nursing, or vaccination, in so far as they come under the purview of the various Government departments. The last part of the index is occupied with a list of the titles and cost of the publications issued by the departments including the Ministry of Health and the Medical Research Council. The Guide grows in value from year to year and has already become an indispensable companion to the reference library. The price is 1*s.* net, or 1*s.* 4*d.* post free.

MacAlister Lecture

ON

DIET AND DIETISTS.

Delivered before the London Clinical Society on July 7th

BY SIR THOMAS HORDER, BART., K.C.V.O., M.D., F.R.C.P. LOND.,

PHYSICIAN-IN-ORDINARY TO THE PRINCE OF WALES; PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THIS is the first MacAlister lecture of the London Clinical Society, and I wish someone more worthy than myself stood here to deliver what is intended to honour the memory of him who left us so recently. Amongst those glowing tributes which were collected into a little book last year for the comfort of his family and his friends occurs the phrase: "Something should be done to perpetuate so fine and beautiful a character." He who said this, one of his most constant associates, doubtless had in mind a larger and more worthy monument than the foundation of this lectureship. Yet I feel that, had he known that the London Clinical Society proposed to show him this special token of esteem and respect, it would have brought him a quiet sense of satisfaction. As to the larger and more worthy monument, that we have already—a monument erected in his lifetime, and very largely as the result of his own patient and indefatigable efforts. I refer, of course, to the Royal Society of Medicine. Of this lectureship, as of the glowing tributes to which I have referred, he knew nothing. But he must have looked again and again at the fine building which houses the Society, must have pondered its meaning, and all it stands for in medicine, and must have rejoiced that the fruit of his labours ripened and was gathered in his lifetime. It is given to very few to see their work crowned in so magnificent a manner, and it must greatly comfort those whom he left behind to realise that he saw with his own eyes the superstructure, as well as the stone which was so well and truly laid long years before.

That great physician, Osler, said of Sir John MacAlister that he had done more for medicine than any medical man had ever done. No tribute could better express what we all feel to-day, and what all who care to read the history of medicine in this country, even in generations to come, will feel concerning him whom we are met here this evening to honour. It may perhaps be allowed to one who follows Osler a long way off to refer to a long and always happy association with MacAlister, and to add one more personal testimony to his unfailing helpfulness and to his constant loyalty. So urbane and so patient was he that he never let even the most junior of the Fellows of his Society realise how trivial were some of the matters taken into his room. The applicant for advice or for assistance always left his presence with self-respect unimpaired; and many times, *too* many times—the vanity of youth considered—with an added sense of importance of the matter discussed. His encouragement was one of the most stimulating things in my life, and will never be forgotten. How many hundreds there are who would say the same, were they standing here to-night and enjoying this great privilege that has been given to me.

THE IMPORTANCE OF DIET.

I have chosen a very commonplace subject for my lecture to-day. It is perhaps well sometimes to speak of commonplace things in medicine and, after all, it is the commonplace things that are the most important. It is a little significant that so long as a man is well he does not regard diet as being an important factor in health, whereas once he is ill, and whatever be the nature of his illness, he immediately considers it the most important factor of all. As is usually the case, both attitudes exaggerate the real facts: diet *is* important as a means of keeping healthy, and it is not nearly so important a therapeutic measure in disease as the lay mind imagines. The old adage, ascribed to Swift, which states that the three best doctors are "Dr. Diet, Dr. Quiet, and Dr. Merry Man," might refer quite as truthfully to the preservation of health as to the cure of disease.

It is always a difficult problem for the doctor who inculcates principles of hygiene to steer between the rocks of too much indifference on the one hand, and too much meddlesomeness on the other. We frequently see wreckages as the result of ignorance or of prejudice taking the helm during this voyage. If I say little or nothing this evening that is novel, it is because of my desire to avoid another wreck. The barque in a precious one, and I would much rather proceed a very little distance, and leave the ship in mid-stream, than boldly forge ahead when not quite certain of the course. There is even another contingency to remember: the sea may be so turbulent, and exact knowledge of the situation of the rocks so uncertain, that there may be no little virtue in keeping the vessel very much where the pilot found it, especially if the bearings are taken, and are made available for the next man who holds the helm. I say this to anticipate disappointment. I am not sure that I am going to do anything more this evening than to take soundings and hope to keep the ship in the fairway.

MODERATION.

As I have said, we are rarely consulted by healthy folk concerning their diet. Even if we were, I am not sure we could tell them very much that they do not already know. I am not speaking of the feeding of babies, which is, of course (or was, until recent years), a matter of special ignorance. Given that the quality of food is good—that it is free from adulteration—and that it is properly prepared for eating, whether by cooking or otherwise, the major part of our advice to the healthy person would probably turn upon quantity. And though we did not use the words, temperance or moderation would really be the key to what we said. And here, perhaps it is well to reiterate a truism—that temperance is not abstinence, and not even parsimony. Milton, in Comus, speaks of all the world feeding on pulse "in a pet of temperance," and it must be confessed that many so-called temperance advocates are a little inclined to be "hot" about their exhortations. But to quote Milton again:—

> "If thou well observe
> The rule of 'not too much,' by temperance taught
> In what thou eat'st and drink'st, seeking from thence
> Due nourishment, not gluttonous delight,
> Till many years over thy head return;
> So mayst thou live, till, like ripe fruit, thou drop
> Into thy mother's lap, or be with ease
> Gather'd, not harshly plucked, in death mature.
> Temperate in every place—abroad, at home,
> Thence will applause, and hence will profit come;
> And health from either he in time prepares
> For sickness, age, and their attendant cares."

That most people eat too much will scarcely be gainsaid. Judged by the known number of calories that the engine requires for efficient work, this is certainly the case. And yet there is no general consensus of opinion as to what this requirement in calories actually is. We have been through a period, enforced by war, when parsimony in this respect gave us an object-lesson which nothing else could well do. There are many fallacies in the conclusions to be drawn, but on the whole there seems agreement that health all round was not much, if at all, prejudiced by the reduction in food calories. Such disabilities as did occur were probably attributable to qualitative rather than quantitative causes. It is taught that there are many conditions that should influence diet, especially in regard to this question of quantity. The nature of a man's work is generally said to be one of the most important of these. It is said that the brain worker requires less food than the manual worker, and that this fact has been established experimentally. I have read the experiments and I am not impressed by them. I do not think it is possible to get satisfactory conditions for such

experiments. Brain work is such an individual thing. One man sits quietly, with very little muscular movement, working out a mathematical problem by the hour. These, by the way, are the conditions generally chosen for such experimental observations as I have spoken of. Another man, active by nature, is alert, talks and moves about, yet, like the other, is doing brain work. It is quite likely that the food calories required by the latter example of brain worker will approximate nearer to the labourer than will those required by the former. If appetite be a guide to food requirement, and it certainly is in health, then it is a fact that many brain workers require quite as much food as many manual workers. That the brain worker does better work with small meals than with large ones is a trite statement; but this refers only to the period of his actual work. That he benefits by a larger meal when his work is done, always provided he be not overtired, many will agree from their own experience. But I think this applies to the manual worker also. A prudent man will adapt his meals to his work rather than his work to his meals, though it probably tends to the greatest efficiency to do both of these things. Thus, some men who take care to economise in regard to these matters choose relatively slight tasks to follow the midday meal—assuming there be a choice, as there often is. This is but a corollary to the ancient boast attributed to Socrates, who said, "Other men live to eat, but I eat to live."

FASTING.

There has of late been quite a little boom in the direction of fasting, and this may perhaps be considered in relation to the quantity of food, since to eat nothing at all is, strictly speaking, a quantitative business. I am prepared to admit the value of fasting for short periods in certain diseases, but in the absence of disease I have never seen any good results from it which may not be obtained by less drastic means. I think there is value in the occasional missing of a meal, or in the substitution for a meal—most conveniently and helpfully the midday meal—of a few biscuits and a piece of chocolate. But the more elaborate and prolonged process of actual fasting which is sometimes advocated, and which requires, for its proper carrying out, a complete or a partial cessation from active work, has never seemed to me to promise any real benefits. The necessary inactivity is clearly uneconomical, and the method is therefore only practicable for the non-workers (with whose diet we need not seriously concern ourselves), or for the worker during vacation times. I do not believe that fasting is of value to the healthy person in the long run. As I have said elsewhere, I fear the pride which follows the pursuit of any such dramatic measure, to say nothing of the risk that so great an exercise of restraint might lead a man to think that subsequent indulgence is safe; for human nature is very frail. Surely it is better to adopt a régime to which one submits not uncomfortably, than to endeavour to enforce one which appeals as a series of unnatural denials. As I have already said, even a three days' fast, however thrilling an experience this may prove for the leisured man, is fraught with much inconvenience, and not a little sacrifice of efficiency, to the occupied one.

In some diseases, as I have hinted, a short fast, the patient remaining in bed the while, and undergoing a preliminary purgation, is often beneficial. Of general diseases arterio-sclerosis and hyperpiesis are examples. The periodic fast-day in the treatment of diabetes, euphemistically termed by some a day of "alimentary rest," has more than justified itself in certain cases. The French method of treating acute appendicitis and some other inflammations connected with the alimentary tract by several days' fasting, allowing only water to drink, is well known.

MEALS AND FATIGUE.

In regard to the times of eating, custom dictates three meals a day, and this fits clearly with known facts regarding the physiology of the stomach. It also splits the working day into convenient and economic periods, allowing the meal times to synchronise with rest-times from work. The injunctions not infrequently heard, to make a habit of going without breakfast, or without lunch, and the declarations of unusual fitness to be derived therefrom are, doubtless, in the main, experiments in individual psychology, with the attendant benefits about to be referred to in connexion with such experiments. I doubt very much if, in the long run, the two-meals-a-day man scores anything in efficiency or in health over his more ordinary brother. I am speaking now of routine, not of the occasional missing of a meal, of the benefits of which I have already spoken.

Fatigue of an unusual kind makes the consumption of a full meal very inadvisable. This is common knowledge, yet one frequently sees the crime committed, with due penalty imposed by nature. Fatigue, exposure to cold, and a heavy meal—these three things coinciding, form quite a common piece of history in the evolution of a number of acute diseases. I need not enter into the explanation. The method of feeding appropriate to excessive fatigue is that which is applicable to a return from fasting—small, warm, and easily digested feeds. The busy doctor, home late from his day's work, "thoroughly done," has had his dinner "kept hot" for him. A solicitous wife has heaped the plate all too generously—for to "feed the brute" is still regarded as a mark of affection—the oven has been rather too hot, or not quite hot enough (either defect contributes its corresponding element of indigestibility to the pile of meat, vegetables, sauce, and gravy), and the weary man "lets himself go" upon the mass. Result, a period of gastric stasis, a restless night, and perhaps all manner of subsequent disabilities. How much better to have given the official dinner a "pass" and substituted a small basin of bread and milk.

There is an affinity between sleep and eating, in the sense that, for efficiency, one is vicarious in respect of the other. The less sleep, the more is food necessary; the more sleep available, the less food needed. The doctor who sits up all night with his patient and then has the good fortune to get a long night's rest next day knows the truth of this statement.

AGE AND SEX.

There seems little doubt that age should affect our views upon diet, and especially in regard to the quantity of food. We should "play for safety" in children, and in all persons at a period of growth, allowing a liberal measure. I remember reading the lengthy report of a pathologist, who obviously had marked views on the subject, in which he attributed some visceral troubles in a man of 40 years to the fact that his mother "fed him up" at the age of 14 when he was convalescing from an attack of measles. I was not at all convinced. At the other end of life however, there is no doubt that both the amount of food, and the frequency of taking it, can ofttimes be reduced with advantage. There is an old proverb which reads: "Who steals an old man's supper does him no harm," and the sense of the saw fits well with experience. The well-known injunction of Bacon is often quoted in this connexion: "Discerne of the coming of the years, and think not to do the same things still, for age will not be defied!" Dr. Robert Hutchison reminds us that whereas leanness and longevity go together, "a man will only roll all the faster down the hill of life if his figure be rotund." It is necessary to beware, however, the tendency of old people to dictate to those who are younger, and to preach a regimen for them that they find by experience well suited to themselves.

As regards sex there is not much to say. There is general agreement that, other things being equal, the female needs less calories than the male. But this consideration probably does not apply to the period of growth. If so, the individu-

requirement may be the opposite of the general rule, and I think this is true. As to frequency, experience suggests that women need feeding at shorter intervals than men; but here, as so often, there are great individual differences seen. There appears to be a definite physiological necessity involved in the early afternoon tea which most women require for the efficient working of at least the nervous part of their economy. No man who loves peace in his home will make it difficult for this meal to be punctual, whether he shares it or not.

Individual Needs and the Evangelical Dietist.

The individual factor in dietetic requirements is a very large one, and there are many fallacies entering into the argument of personal experience as a guide to diets for all and sundry. So often we hear a patient say that he pursued a certain line of diet on the advice of a friend, but that it did not suit him; or we are asked if such and such a line of diet is likely to prove beneficial. It is a futile business from the first. The patient is perhaps a brain worker with a large output of highly responsible and technical work; his friend is a dilettante with a small output which involves no issues to speak of and is devoid of meaning. The patient is tall and lean and suffers from neurasthenia; the friend is short and stout and has a high blood pressure. These are but a few of the possible fallacies. There are many others. There are fallacies of race, of climate, of occupation, of habit. What boots it to the citizen of twentieth-century London that the Eskimo lives on a pound or two of blubber daily, that the Hindoo exists on rice, or even that the Scottish crofter manages to live and work on oatmeal? (As a matter of fact he does not live on oatmeal; he lives on oatmeal and milk, but the milk is conveniently —I must not say unscrupulously—omitted to serve a favourite thesis.) We ought to distrust all these stupid so-called arguments.

There is the constitutional fallacy, too. "Look at me," says the advocate of some dietetic fad, "see how fit I am." Very often he is fit in spite, and not because of, his cranky diet. He was *made* fit, and nature's almost infinite capacity for adaptability enables him still to remain fit, his odd dietetic rules notwithstanding. There are some folk who are so fit by nature that good health almost hurts them; it is a positive danger. There are others who only attain, and keep, fitness by a constant struggle. "Do you not think, doctor," said a woman, the very sight of whose robustness made it evident that she belonged to the former class, "that it would help my husband if he were a vegetarian, as I am?" The husband was small, weakly, and full of minor disabilities of a nutritional kind. "Madam," I said, risking a mortal offence, "I perceive that you can afford to be a vegetarian." It is as old as Lucretius, probably older still, that "one man's meat is another man's poison" —*rank* poison, Lucretius is reputed to have said. The dictum has been restated by many wise men down the ages.

Then there is the psychological fallacy, at which I have already hinted; it is a very large and very common one. The man with a theory—if odd notions about diet may be distinguished by so scientific a term—is already half way towards a successful experience. He attributes to his practice what is really due to his enthusiasm. He has the endurance of the martyr and he burgeons upon his idea rather than upon his regimen. The fakir fasts for weeks, and appears to thrive; he is filled by a fervid afflatus which gives him unnatural strength. But the plague seizes him and he falls a ready victim. True, he succeeds, because he enters his paradise a conqueror of the flesh. But this is neither medicine nor science. It has been my experience to meet several strange advocates of great parsimony in diet. One was a writer of some distinction; I can see him now, pacing up and down my consulting-room, waxing eloquent ment the clear vision and the spirituality of thought which he secured as the result of semi-starvation. I was able to recognise in his eye and manner an ecstasy which, I have little doubt, was not unrelated to his felo-de-se, which I saw recorded years afterwards in the papers as having taken place in America. I have helped to resuscitate from states of inanition two of our own profession, loud and influential exponents of diets in which the *maigre* element was paramount. One of them was fed every two hours on beef-tea, fortified by raw meat-juice, until the thermometer registered something that really showed him to be a warm-blooded animal, his pulse reached the "50's" and he ceased to babble o' green fields. It fills me with despair to know that he is once more teaching that meat is a poison, that milk is little better, and that the proper diet wherewith to combat all the ills that flesh is heir to is raw fruit and raw vegetables.

Speaking of fruit reminds me to say that there appear to be two values in this as an article of diet. In the first place, consisting as it does, in most instances, almost entirely of water, its consumption provides for more water in the diet—an almost universal benefit. In the second place, people believe it to be a food, and therefore in eating it they unwittingly reduce the total bulk of their diet; another manifest advantage in many cases.

Ill-Effects attributed to Diet.

I now turn to the consideration of a very important question—that of diet as a factor in the production of disease. There are few established facts in this connexion, and there are many rather wild statements which are based neither upon experiment nor upon experience. Let me confine myself at first to the possible ill-effects of ordinary wholesome and mixed dietaries. We know that a "luxus consumption" tends, in certain individuals, but by no means in all, to gout and obesity. We also know that the repeated mechanical distension of the stomach by a large bulk of food may lead to its dilatation, perhaps permanently. A surplus of sugary and of starchy foods sometimes produces diabetes in predisposed persons. Perhaps—but only perhaps—excess of protein food may tend to kidney disease. But here our knowledge, or our half-knowledge, ceases. And it will be seen that the evils are due to excess in the total amount of food, or excess of some particular type of food: the error is a quantitative one. If now we pass to consider diets which are restricted in some of their principles, or which are changed in certain essential particulars by the action of heat and certain chemical agents, we find that a group of so-called deficiency diseases may result from the deprivation of vital substances termed vitamins or accessory food factors. We are not yet certain how many morbid conditions are included in the deficiency diseases, but so far as research has gone, it is probable that the list at least includes beri-beri, scurvy, rickets, and keratomalacia. Normal growth, too, seems to depend to a considerable extent upon these or similar substances being present in food. It is established that very little of these substances is really necessary to prevent these diseases: the bodies concerned appear to be of the nature of ferments, or (better) activators of assimilation and perhaps of metabolism. The notion that has been promulgated of late, therefore, that great care must be taken in order to ensure a sufficient supply of vitamins in the diet of the vast majority of people in this country is absurd. Very little suffices for the purpose, and it is certain that the common mixed diet of most households contains sufficient and to spare of all the vitamins without special precautions being exercised in this direction. Plagiarising Prof. W. M. Bayliss, I might say, "Take care of the mixed diet and the vitamins will take care of themselves." This is the science of the position as far as we know it. And yet I read some advice the other day in which the doctor exhorted the patient to "fill himself up with vitamins," as though they were like the beer of the familiar drinking song!

WHOLEMEAL BREAD.

Much of the advocacy of wholemeal bread turns upon the fact, an undoubted one, that, bulk for bulk, it contains more vitamin B than does white bread. This fact becomes of very minor importance, however, when we remember that other common foods are very rich in this same vitamin—namely, eggs, peas, beans, lentils, and nuts. The most serious error introduced into this same advocacy of wholemeal bread is the impression given that white bread contains none of this vitamin at all. The truth is that, although white *flour* is practically free from vitamin B, yet, since yeast is extremely rich in this vitamin, white *bread* contains it. Both forms of bread having been subjected to the same degree of heat, neither has an advantage over the other in regard to the partial loss of vitamin on this account.

How comes this fallacy about? I can only suggest that there has been an absence of clear thinking on the part of those who have taken up this campaign in favour of wholemeal bread.

I suspect that the advocacy of this bread was begun on the ground that the extra cellulose which it contains, forming what has been termed "roughage," is of advantage as a mechanical irritant to the mucous membrane of the colon, and scours the intestine by bulking up the stool. Enthusiasm would appear, then, to have seized upon the fact that white flour is free from vitamin B, and to have loosely converted this into the statement that white bread is also free from vitamin B, thus adding—but quite erroneously—another supposed benefit to wholemeal bread.

In short, the undoubted benefits to be derived by some people from wholemeal bread as a means of avoiding colonic stasis have become confused with the question of the nutritive value of this article of diet. Even if it were true that the chemical composition of wholemeal bread proved that it had a higher nutritive value than white bread, which, as a matter of fact, it does not, this would give no guarantee that the person who eats it secures this additional possible nourishment. Because the net effective nourishment obtained from any article of food depends quite as much upon the form of its presentation to the digestive organs as to its ultimate chemical composition. More than a certain amount of cellulose is actually deterrent, both to the process of digestion, and to that equally important function, assimilation. In the first place, this cellulose prevents the free access of the digestive juices to the nutrient principles of the food. In the second place, the mechanical irritation of cellulose which is at all hard, and in the state of "roughage," causes a reaction on the part of the mucous membrane of the bowel, whereby there is a flow of fluid of a valuable kind into the lumen of the gut, so that much of the nutrient material is carried away in the fæces. Not only must we consider the mode of presentation of a food to the digestive organs themselves, but we must also consider the mode of its presentation to the eye, the nose, and to the palate. The psychological element in food values has been known, both physiologically and gastronomically, for a long time, but it has been largely omitted from the teaching of some recent writers. This is an important consideration in the question of the relative values of wholemeal and of white bread, to say nothing of its bearing upon the asbestos-resembling material which has been much vaunted of late. It is clear, therefore, that the whole question of the relative values of white and of wholemeal bread is much more complicated than the public is led to suppose by reading recent propaganda, much of which, I feel impelled to say, is the outcome of an ill-informed enthusiasm, rather than of considered judgment after a proper survey of all the facts.

Even so the matter does not end here. If we turn for a moment to economic considerations we find that, bulk for bulk, white bread possesses more actual calories available for nutrition than wholemeal bread, so that, even if the two articles were obtainable at the same price, which at present they are not, the average citizen may stand to lose more than he gains by the substitution of the latter for the former. Seeing that, as already stated, his vitamin B is amply assured in other directions, there only remains the dubious advantage of the scouring effect of the wholemeal bread to which I have referred. The question remains, does the average man require this "roughage," and, if he does, is it a good thing in the long run that this roughage should be introduced in the form of what, after all, is his principal article of food rather than in some far more subsidiary article? This last consideration is quite possibly the crucial one in the whole matter I am now discussing.

COLONIC STASIS AND ITS RESULTS.

The question cannot be taken further without touching upon the subject of the transit of food through the alimentary tract and the associated subjects of the frequency and the consistency of the stools. Clearly, nutrition is not a matter of how much food-value is put into the mouth, but of how much of this food-value is made use of in the body. If a large part of it leaves the body in the fæces, then apart from the possible psychic benefit to the person derived from the knowledge that he is having so many actions of the bowels per diem—and this psychic benefit will depend upon what he is taught as to the criterion of health in this respect—he is actually the loser, and not the gainer, by the particular choice of food which leads to this result. Certain recent teaching on these matters has influenced the public in such a way that even the regular passage of a formed action once a day leaves many of them in a state of apprehension lest some evil befall them. Personally my own observations lead me strongly to the opinion that the consistency of the stool is of greater importance than its frequency. There are, we know, some individuals who never pass formed stools, and this independently of diet and medicines. But the average healthy man does pass formed stools; this can scarcely be gainsaid. I find it very difficult to believe that to convert this normal type of stool into one of more fluid consistency—whether by choice of food or by medicaments, call them aperients or lubricants, or what we will—is to confer any known benefit upon healthy persons. What is the nature of the benefit which such a change is supposed to confer? We are told that this change prevents colonic stasis and that colonic stasis is a precursor of a whole series of diseases, including cancer. I propose to deal with these claims in the light of such knowledge as we have on the subject.

In the first place, I would remind you that some degree of colonic stasis is physiological; to take steps to avoid it entirely is, therefore, unreasonable. The slowing down of the passage of the intestinal contents through the colon allows of the absorption of water, perhaps also of nutriment, and secures the moulding of the mass so as to form a stool which can be easily dealt with by the musculature of the pelvic colon and of the rectum in the act of defæcation. Colonic stasis, then, is not pathological unless it becomes so marked as to leave a residue in the cæcum and in the ascending and transverse colon, in such a way that efficient and regular drainage of these parts does not take place. Clinical observation, aided largely by radiographic investigations, shows that in many patients coming to us for treatment such pathological stasis does occur. But in other patients, in whom similar observations and investigations prove that there is habitually an unduly hurried clearance of the colon by rapid transit of the intestinal contents, we do not see any corresponding benefit accruing. On the contrary, such patients are liable to ills of their own, not less in degree or in significance than in the case of their more sluggish fellows. It is a fallacy, therefore, to teach that good health is in all persons proportionate in any sense to the rapidity of transit of the intestinal contents through the colon.

When we come to the second part of this teaching we have to record that there are no established facts at all which justify the notion—I will not distinguish it by the term hypothesis—that such

liseases as peptic ulcer, appendicitis, and cancer result rom, or even tend to result from, a slow passage of he intestinal contents through the colon, still less rom what may be regarded as the known physiological ate of this passage. That this is true is of the utmost mportance in view of the public apprehension in egard to cancer especially. This apprehension has ecome seriously increased as the result of propaganda elating to "intestinal intoxication" and its supposed aleful effects.

In this connexion I have more than once pointed ut that, far from colonic stasis and constipation eing known precursors of cancer, the evidence points lefinitely in the other direction. The type-case of ancer of the colon is *not* the case of a chronic colonic lyspeptic, but of a patient whose intestinal functions ave been quite good up till the time when it may be resumed from our knowledge of the growth of arcinoma in this situation that the neoplasm began. gain and again are we told by patients that until bout this point in the history of the case, the bowels cted regularly and well, and without the use of perients. Cancer of the colon is more frequent in nen than in women, whereas colonic stasis is much nore prevalent in women than in men. Again, the ubject of chronic intestinal dyspepsia seems to levelop cancer quite infrequently. On the evidence efore us, therefore, it would be just as logical to reach a slowing-down of the intestinal contents as a rophylactic measure against cancer as to inculcate he doctrine which I am now criticising. The same rror has crept into considerations of the pathology of astric cancer. We are told that gastric ulcer and hronic diseases of the stomach tend to cancer of this rgan. The evidence points entirely the other way. he chronic gastric dyspeptic, whether his or her rouble be peptic ulcer, or dilatation, or gastritis, only evelops cancer in relatively few instances; whereas ancer of the stomach, arising without any history of revious dyspepsia, is a very common disease.

It is quite seriously alleged that there is radiographical evidence in support of the teaching that ancer is an end-result of colonic stasis. I have never een able to ascertain what this evidence is, and I egard the allegation as being entirely without foundation.

PERPLEXITY OF THE PUBLIC.

The public has been put in a dilemma, and by the ame school of doctrinaires. On the one hand it is arned against even the mildest aperients, and is told hat to use these involves a danger of cancer; so hat I now get letters from patients asking me if they hould, on this account, give up the taking of (say) he pinch of Epsom salts every morning which seems o have helped to keep them in health for many years. n the other hand, the public is warned with equal eriousness that if it does not secure three or four ctions of the bowels a day the danger of cancer is ven greater! So that some patients, again, with this read in their minds, are certainly living on the edge malnutrition. Surely it is time a health society ose which spread a less confusing and a more omforting gospel; it might be called the Society of ommon Sense. To begin with its main thesis might e to leave well alone. Later it might embark upon me simple but well-established principles of hygiene, aving alone all personal and highly debatable ideas. ccording to the teaching which I am now combating e whole duty of man in respect of his diet would em to be summed up in this dictum: Put very tle into your stomach and take care to get it out ain as quickly as possible.

It is surely a grave responsibility to attempt to oselytise in the name of science, instead of making clear that what is advocated with such fervour is ly a form of personal belief? Laymen have been ld that upon the selection of their food turns, in a ge measure, their chance of developing cancer; t we know no single fact whatsoever concerning the usal association of diet with cancer. True, the idea iginated largely in the mind of a layman. But fortunately laymen have been encouraged to write popular books and articles on this subject under the ægis of medical men—a glaring instance, as I have already pointed out, of qualified practitioners giving "cover" to unqualified men.

DIET IN DISEASE.

I have not time to-day to deal with diets as applied to actual diseases. There are, as we all know from personal experience, many "cures" vaunted as infallible remedies for nearly every disease. I have already referred to the fact that it is a common belief that there *should* be a special diet for all ills. No question is asked more often in our consulting-rooms than "What may I eat, doctor?" It not infrequently happens that a patient, suffering from a malady of many years' duration, insists upon hearing before he departs what he may have for his lunch that day. And it is pathetic to watch his face light up as we detail some very safe and easily digested dish. These people are an easy prey to the diet-monger who claims a panacea for every malady. With one such enthusiast it is the Salisbury diet, with another fruit, with another raw vegetables. And all patients get the same diet from the same source. The tall, gaunt, woman, with enteroptosis and neurasthenia, gets the raw turnips and carrots together with the plethoric city magnate. The badly-nourished patient with rheumatoid arthritis gets the same instructions as the arteriosclerotic with hypertension.

I am moved, when I come across this kind of thing, to a spirit of thankfulness that the classical text-book dealing with the subject of food in this country comes from the pen of a man possessed of the inestimable gifts of common sense and judgment. Dr. Hutchison says it must not "be supposed, as the laity are apparently tempted to do, that diet is a universal panacea which can be counted upon to prevent or to cure all diseases. On the contrary, it has, like other remedial agents, only a limited place in therapeutics." If such forbearance in thought and in expression were a more common attribute in some of those who undertake the serious and responsible task of instructing the public in hygiene, though they may not say so much, their influence would be exercised to much better purpose, and redound more to the credit of medicine.

An Address
ON
THE POOR-LAW HOSPITAL AND ITS RELATION TO GENERAL PRACTICE.

Being the Presidential Address delivered to the West Kent Medico-Chirurgical Society on May 13th, 1927,

BY HUMPHREY NOCKOLDS, D.S.O., M.B., B.S. LOND.,
MEDICAL SUPERINTENDENT, LEWISHAM HOSPITAL.

IN 1867 the Metropolitan Poor-law Bill was introduced into Parliament. This Bill provided for the classification and separate treatment of the sick by the establishment of workhouse infirmaries, recommended the employment of paid and qualified nurses, and directed that all medicines and medical appliances should be supplied by the guardians and not out of the salaries of the medical officers, as heretofore. It is indeed astonishing in these days to realise that at one time institutional medical officers had to supply drugs and appliances at their own expense, so that the worse he performed his duties the more salary he was able to make.

EVOLUTION OF LEWISHAM HOSPITAL.

This spirit of minimal activity in the treatment of the sick in Poor-law institutions has, however, survived until quite recent date. We now turn to Lewisham Hospital, and it may be interesting to glance at the stages of its evolution.

Before the year 1894 the sick poor of Lewisham were treated in the voluntary hospital and in the sick wards of the workhouse. In April, 1886, the Local Government Board sent their inspector to discuss with the guardians the great need of additional accommodation for sick, as the sick wards of the workhouse had been very much overcrowded during the past winter. In the following August the officials of the Local Government Board advised that a separate infirmary—i.e., entirely separated from the workhouse—was absolutely necessary. By December, 1886, there was no further room in the workhouse for patients, and some were boarded out with other unions. In July, 1887, the guardians submitted a scheme for converting one of the workhouse blocks, together with the erection of two additional blocks for the sick, in order to avoid the purchase of land and the erection of a separate infirmary. The Local Government Board would not sanction this, and pressed the guardians to proceed with the more ambitious scheme, pointing out that Lewisham had a rapidly increasing population for which to cater.

In November, 1887—i.e., after one and a half years of discussion, the guardians decided to provide a separate infirmary. In May, 1888, the Local Government Board again called attention to the state of affairs, that the existing medical and nursing arrangements were quite inadequate. Finally, site, plans, contracts, &c., were all arranged, and the completed building was opened on Oct. 10th, 1894 (eight and a half years after the shortage of accommodation had been felt), with a certified accommodation for 379 patients. There was a medical superintendent (Dr. F. S. Toogood) and one assistant medical officer. It is interesting to note that no provision of any kind was made for an operating theatre. As a matter of fact I believe that it is true that of all the Poor-law hospitals of London not one had an operating theatre designed at the time of building! At this time the building was called the Lewisham Union Infirmary for the Destitute Poor. Also about this time the total population of the Lewisham Union was about 106,000 (1896). About 1899 the mental wards were added; otherwise there has been no increase of accommodation by new buildings up to the present time.

After the war the workhouse was abolished and the accommodation given over for extra nurses, maternity and antenatal clinic, and ordinary sick wards—accommodation very unsatisfactory and quite out of date. Now you can see the new hospital block (278 beds) and new nurses' home well on the way to completion. These wards are quite modern and up to date in design, and are hospital wards and not the old-fashioned infirmary wards. These extensions conform to the policy suggested by the Ministry of Health. "Any extension approved at the present moment must not only be justified by immediate needs, but should be of such a character that they are likely to meet the needs of a reconstituted health authority (including Poor-law) for the area" (Annual report of the Chief Medical Officer of the Ministry of Health for the year 1925, p. 194, para. 404.)

It is also hoped in the comparatively near future to adapt the old buildings to make new receiving wards, out-patient clinic, new X ray room, &c., as the accommodation in this respect is highly unsatisfactory. That this fresh accommodation is needed is quite obvious from our chronically overcrowded wards and from the fact that the population has just about doubled since 1894 (212,000) and is still rapidly increasing.

Equipment.—In the early days of the separate infirmary the equipment was of the barest—no theatre, no special departments or aids to diagnosis. And the task of the then medical superintendent must have been depressing to a high degree. Slowly but surely he began to develop the place, improvised an operating theatre, and brought the institution up to the standard that many knew well before the war.

SURGERY AT THE END OF LAST CENTURY.

Modern surgery, especially in regard to abdominal operations, had not in 1894 come fully into its own, and indeed hardly did so before the new century commenced. Poor-law infirmaries at that time were many years behind the times, and the thought that the diseases of the destitute sick poor required the same facilities for treatment as those of others appeared to be overlooked, and little else than bed, food, and a certain kind of nursing was available. In any case, had facilities for treatment been available, the scanty medical staff would have been quite unable to cope with the number of cases. In these early days, therefore, those who could went for treatment to the voluntary hospitals and did all they could to avoid the pauper taint. Hence there was a tendency for the old, infirm, and chronic cases to gravitate to the infirmary, and for the acuter cases to go elsewhere, where the facilities for treatment were known to be better. It must also be borne in mind that for many years the training of nurses in Poor-law hospitals was non-existent. As early as 1860 Florence Nightingale had opened a training school for nurses at St. Thomas's Hospital. It was not until 1881 that training schools for nurses were established in Poor-law infirmaries. In 1902 was published a report of the Departmental Committee appointed *ten years previously* to consider matters connected with the Poor-laws, especially in connexion with the nursing of the sick, and at long last the Nursing Orders of 1913 were promulgated by the Local Government Board, in which all superintendent nurses or matrons were required to hold certificates of three years' training in the wards of a hospital or infirmary which was a training school, and also to hold a certificate as midwife under the Act of 1902.

We may well pause for a moment to consider how it was that such a long period of minimal activity as from 1860 to 1913 in the progress of the Poor-law medical and nursing services was possible, more especially if we compare the post-war interest and progress. The following factors, in my opinion, have considerable bearing. In the early part of this period medical, and more especially surgical, treatment had not reached the stage of development which necessitated the presence of the patient in a hospital ward, surgery especially being confined to comparatively few operations, which were performed by a limited number of surgeons. The voluntary hospitals could therefore meet this need entirely. The taint of pauperism and the traditions which developed from the Poor-laws of about 1601 (in those days any pauper who left his parish was liable to be whipped at the cart-wheel) has, until very recent times, prevented the sick from seeking accommodation in Poor-law infirmaries. The penalties meted out to the able-bodied poor and to the sick poor were practically the same, loss of the franchise, and so forth. Therefore it would appear to be fairly obvious that no inducement was given to the poor to make use of these institutions in sickness, except as a last resource; which attitude of mind and ideal of service is the very antithesis of that which should pervade a service designed for the alleviation and cure of disease.

POST-WAR PROGRESS IN POOR-LAW INSTITUTIONS.

Now we may turn with a certain amount of relief to the present. And we may now ask why is it that the post-war progress in Poor-law institutions for the sick has made, at any rate in London (I know little of the provinces), considerable strides, and are now catering for such a large number of acute cases—not a gradual alteration in the curve towards efficiency but quite a sharp rise.

1. The overcrowding of the voluntary hospitals—the fact that they had not expanded with the need of the population, and that hospital in-treatment is growing in scope and a comparatively large percentage of the populace are admitted either for investigation or treatment. This congested state of the voluntary hospital inevitably throws more work on to the Poor-law hospitals, at any rate in Lewisham, and especially of the class of case known as "acute abdomen" and other cases of the very urgent type.

2. I think that there is a greater inclination for patients to go into hospital than before the war. During the period of military operations vast numbers of the male population passed through hospital, many of them converted Poor-law institutions, and so have got used to hospital life. Further, many of the Poor-law hospitals have never gone back to the pre-war standards, are now named hospitals, and the common people enter them with greater confidence.

3. The most important factor, however, in my opinion, which has contributed to the progress of Poor-law hospitals, has been that enormous growth of humanitarian and altruistic feeling in general

which has taken place in England during the last century, and which has suddenly, so to speak, burst into flower. Whether *all* the manifestations of this humanitarian growth are to the advantage of the race is not a matter for present consideration, but that it is part of the moral equipment of modern man can hardly be denied. Trotter ("Instincts of the Herd in Peace and War," second edition, p. 124) says: "Throughout the incalculable ages of man's existence as a social animal, nature has been hinting to him in less and less ambiguous terms, that altruism must become the ultimate sanction of his moral code. Her whispers have never gained more than a grudging and reluctant notice from the common man and from those intensified forms of common man, his pastors, and masters . . . and when it has been interpreted to the people it has always been received with obloquy and derision, with persecution and martyrdom. Thus, as so often happens in human society, has one manifestation of herd instinct been met and opposed by another."

It is interesting to cast one's vision back a moment for 100 years.

. . . Mr. Justice Park at the Spring Assizes at Salisbury in 1827 said, that though the calendar was a heavy one, he was happy to find on looking at the depositions of the principal cases, that they were not of a very serious character. Nevertheless he passed sentence of death on 28 persons, among them being one for stealing half-a-crown! (W. H. Hudson, Collected Works, 1923, "A Shepherd's Life," p. 225.)

What a change has taken place in 100 years! I have perhaps strayed a little from the path, but have done so to try to show what powerful and at times partially unnoticed forces guide the destinies of the human race.

Poor-law Hospitals Expanding.

Now we must consider in more detail what have been the happenings in Poor-law hospitals since the war. The first thing one notices is a large number of medical superintendents of Poor-law hospitals, with their mouths wide open and like Oliver Twist, asking for more! More medical officers, more nurses, more beds, better equipment, more aids to diagnosis and treatment, and so on, and I think that in spite of many obstacles and difficulties, much has been accomplished, and to find illustration we come back to Lewisham Hospital.

The resident medical staff before the war was three in all with no part-time consultants. Now there are five resident medical officers, one of whom does part-time as district medical officer to one of the divisions of the union; three part-time consultants, physician and surgeon and radiologist; and also we have the help and advice of the pathologists at St. John's Hospital, who at present do our pathological work at their own laboratory. Further, power has been given to the medical superintendent to call in any other consultant that he may choose at a fixed fee per visit. The value of these arrangements is incalculable, but they mean extra work for the resident staff, and not *less* work.

There is now an antenatal clinic held weekly to enable those on our maternity books to be examined from time to time. The nursing staff has been considerably augmented in numbers and the training school made more efficient by the appointment of a sister tutor, who devotes the whole of her time to the training of the nurses.

The ambulance service, which before the war consisted of one horse-drawn vehicle, is now provided by three well-equipped motor ambulances.

The X ray department was non-existent before the war; now some 2000 X ray examinations are made yearly, representing actually about 1000 patients examined, and it is hoped to move the X ray department to more commodious quarters and to bring the apparatus fully up to date and to increase the scope of the work by doing X ray treatment.

There was no massage department before the war; there are two fully-trained masseuses now. There again, it is hoped before long to find better accommodation and to add artificial sunlight treatment, &c., to its activities and to increase the facilities for electrical treatment, exercises, &c.

The pathological work done before the war was very meagre in extent. Now, facilities for extension of this work were arranged with St. John's Hospital, but it is hoped that in the not distant future we shall have a fully-equipped laboratory of our own. One method by which the congestion in the wards is relieved is by referring in-patients to the out-patient department for continuation treatment, and many cases can thus be discharged earlier than otherwise would be possible. This work is done by the medical officer who does the district worked in connexion with the hospital.

A very considerable number of casualties are brought to the hospital for emergency treatment—at the rate of more than 2000 annually. The London County Council ambulance in 1926 made nearly 1000 visits to the hospital. No proper organisation or department exists for this work, but it is hoped that proper arrangements will be made at some future date.

I have already mentioned the new building scheme which is now far advanced, and will here only mention the operating theatre accommodation. It is an astonishing thing to me that so few of the London Poor-law hospitals have adequate operating theatres. I believe that in all they are adaptations of rooms or of post-war date. I once mentioned this to a highly-placed official, and he said they were not called operating theatres, but were worked in as "operating rooms"; presumably that undue attention might not be called to the fact that the Poor-law infirmary medical superintendents were trying to do their jobs! At Lewisham a side ward was adapted as operating theatre without proper light or ventilation and with no anæsthetic room; in this theatre at present some 1200 to 1300 operations are performed yearly. Now, within a few months, a really first-class theatre, with all its necessary adjuncts, will be available, adding enormously to the comfort of the patient and efficiency of the surgeon.

THE GENERAL PRACTITIONER AND THE POOR-LAW HOSPITAL.

Now at long last we come to the general practitioner. What are his relations to the Poor-law hospital? He is our father and our mother, for surely he supplies us with all our sustenance. He is the person who overcrowds our wards and who sends in patients at all hours of the day and night! And from a practical point of view—especially in places such as Lewisham, which has no very large number of voluntary hospital beds within reach—it is the needs of the general practitioner which have to be met. And I foresee that this state of affairs will become more evident, and that a greater number of Poor-law hospitals throughout the country will have to adapt themselves to the needs of the local practitioners, as it seems doubtful whether the increased accommodation needed for the future will be entirely met by increased voluntary hospital accommodation.

Methods of Admission.

It may now be useful to glance at the methods by which patients were formerly admitted.

Theoretically no case should be admitted to Lewisham Hospital except on an order signed by a relieving officer and countersigned by the district medical officer—that is to say, that an ordinary general practitioner has to have his case "vetted" by the district medical officer before it can be admitted to hospital; the only exception to this rule (other than legal transfers, admissions through the clerk to the guardians, &c.) are in cases of sudden and urgent necessity, when the medical superintendent of the hospital may admit on his own order. Just imagine the waste of time, the delay to the patient, and the bother to everybody if such a rule were still enforced!

The methods employed at present are as follows:—

1. The doctor sends a certificate of recommendation to the relieving officer, who issues the necessary order for admission to the hospital and arranges for the ambulance if needed.

2. The doctor rings up the medical superintendent or his deputy at the hospital in very urgent cases, leaving a certificate of recommendation for admission as an *urgent* case at the patient's house. The medical superintendent then despatches the ambulance, but having had no opportunity of seeing the patient he cannot form any judgment of its urgency and has to rely entirely on the opinion of the general practitioner, so in the end it is really he—the general practitioner—who decides whether the patient is a case of "sudden or urgent necessity." All cases admitted thus are technically made paupers, but the only thing they forfeit now is the capacity to become a guardian or a councillor.

At Lewisham Hospital soon after the war an arrangement was made by which urgent cases, willing to pay the full cost of maintenance, could be admitted on the recommendation of a general practitioner by

an order signed by the medical superintendent, thus avoiding dealing with the relieving officer and being subjected to a none too pleasant inquisition. This arrangement, I feel sure, has relieved doctors many times of the anxiety of finding immediate accommodation for an urgent case who is desirous of avoiding going through the relieving officer. The money for maintenance is collected by the hospital almoner.

Now the Poor-law hospital is like the widow's cruse, apparently inexhaustible in the matter of beds; it can never say "house full"—that is to say, cases other than infectious cases are never refused, and this entails constant overcrowding of the wards with extra beds, so reducing materially the air space per patient—none too much in the older Poor-law hospitals—besides being an extra tax on the nurses of the ward. Thus we see that the general practitioner always has access to beds in these hospitals for his patients, and that the mode of entry on the whole is extraordinarily easy, very much easier than ringing round the London hospitals to find one which will (1) take the type of case or (2) has a bed to put it in. Voluntary hospitals can pick and choose and, as far as I know, never put up extra beds. It is to the Poor-law hospital that the general practitioner sends most of the mental cases which come his way; the method of entry under legal restraint for observation and possible certification is the quickest and easiest way for a doctor to deal with an urgent case of mental derangement.

At Lewisham Hospital the mental wards have been shut down because of the structural alterations taking place, and the mental cases of the Lewisham area seeking Poor-law relief have to be taken to St. John's Infirmary, Highgate. Any mental cases inadvertently coming to Lewisham have to be put in a general ward pending transfer, a most undesirable state of affairs.

USES AND ABUSES OF THE PRIVILEGE OF EASY ACCESS.

Now to what uses and abuses does the general practitioner put this privilege of easy access? He can without fail get his urgent cases—especially those demanding immediate surgical or obstetrical interference—into hospital (in the case of Lewisham, fairly centrally placed). His patients can be swiftly and easily moved. If time permits he can run in and see his patient from time to time. Visiting times for relatives are easy and generous, and they meet many of their friends during an afternoon's visit to the hospital. The general practitioner thus can very quickly rid himself of the responsibility of these urgent cases (a responsibility which, of course, he cannot go on holding after his diagnosis has been made), always provided that the Poor-law hospital to which he sends his patients has both the staff, equipment, and skill to deal with the case. Therefore I repeat that the needs of the general practitioner, especially when perhaps rather isolated from the voluntary hospital accommodation, are important factors in the development of Poor-law hospitals.

Now—I feel a little like Daniel in the lions' den—now we come to the abuses to which Poor-law hospitals may fall a prey, and to the errors which the general practitioner may make from time to time.

1. The admission of dying patients; this is only too frequent. The number of cases which come in and die within a few hours is out of all proportion to the number of mistakes of diagnosis or prognosis, into which errors, of course, we are alike liable to fall.

2. The moving of cases which should not be moved or should only be moved at the right time. Cases of sudden hæmoptysis, hæmatemesis—these patients should not be moved indiscriminately, but only after some rally has taken place. Many times have I been asked to take in this type of case at once. Pneumonias are often sent in at the time of the crisis; in my opinion an absolutely fatal thing to do.

3. Cases of abdominal disease are sometimes sent in and morphia has been administered beforehand. This obscures physical signs, and the doctor does not always inform us of what he has done.

4. Cases sent in at unreasonable times. This class of case is unfortunately a large one, and practitioners sending ordinary cases in at times which cause absolutely unnecessary disturbance of the patients in the wards give extra work to the already depleted night staff, may cause an ambulance driver to be got out of bed, and the medical officer robbed of his well-earned rest. To give an example. An ordinary case of quinsy was once sent to the hospital at 12 midnight. It is with extreme frequency that ordinary cases are sent in after the ordinary working day is done and when the receiving ward staff has gone home. One gentleman has a fine reputation amongst us for sending in his cases on Sunday.

5. Practitioners, I regret to say, sometimes fail to notify us of the fact that the patient is either suffering from or is a contact of some infectious disease. As examples, one case was sent in labelled as cholecystitis; she was really suffering from gonorrhœa, and told us that her doctor had told her that if he gave the right disease the relieving officer would not give her an order. On one occasion a maternity case was sent when in labour and no mention was made by the doctor, although he must have known that she was also suffering from secondary syphilis.

6. Mental cases are from time to time sent in as neurasthenia, and whilst realising the difficulties associated with this class of case, I would ask you to consider the effect that the admission of a case of this sort has on the morale of the other patients.

7. Patients are from time to time sent in without being examined at all, and others, although they have not been seen for some days. There is absolutely no excuse for this.

8. Cases are sent in with inadequate information supplied; a good example is that of maternity cases on which some operative measures have already been carried out.

9. In my opinion practitioners are too fond of telling the patient what is going to be done to them in hospital. They even sometimes direct what is to be done, and I will give you a striking case. A maternity case was admitted with a certificate from a doctor stating that it was a case of obstructed labour, and was sent in for Cæsarean section. Unfortunately, besides sending us directions as to what to do, this doctor told the husband that the patient was going to have Cæsarean section in order to get a living child. As a matter of fact the case was one of hydramnios, with an enormous amount of amniotic fluid, and when this was allowed to drain away the patient, after a very short normal labour, delivered herself of a small macerated, anencephalic fœtus. It was no easy matter to explain matters satisfactorily to an already much harassed husband!

It may here be suggested that it is very unwise to place too much credence on what a patient or his relatives say that the doctor said. For my part I disbelieve the average patient in this respect on principle, so often does he put into the doctor's mouth what he himself thinks and sometimes believes.

10. During dense fogs I am always astonished at the practitioners who want an acute chest case moved to hospital.

11. Sending suckling babies for comparatively trivial treatment as in-patients should be avoided, as either the mother has to come to the hospital to feed the child or else it has to be weaned, neither of which alternatives is satisfactory.

12. Finally, certificates sent to relieving officers are not always marked urgent when the case really is so. Only recently a case marked (?) perforated duodenal ulcer was not marked urgent, and several hours of unnecessary delay occurred before the patient was sent in. Luckily the case turned out to be something else.

I have not touched on the future of the general administration of Poor-law and the changes that are likely to take place in the near future. These things are outside our consideration this evening, and whatever changes do or do not take place the Poor-law hospital—perhaps under another and more dignified name—will still exist and the general practitioner will still remain, with his increasing demands upon its beds.

WEST MIDDLESEX HOSPITAL.—Brentford guardians are proposing to add 81 beds, a new maternity block, and more accommodation for electrical treatment to the West Middlesex Hospital, which already holds a good record for up-to-date methods.

CROYDON GENERAL HOSPITAL.—The King and Queen visited this hospital recently, when the Queen unveiled a stained-glass window commemorating her visit. Their Majesties made a tour of the new hospital buildings which includes a new out-patient's department, opened shortly before their visit by the Archbishop of Canterbury. The cost of the building was £30,000.

THE INCIDENCE OF INTRATHORACIC TUMOURS IN MANCHESTER.*

BY J. B. DUGUID, M.D. ABERD.,
LECTURER IN PATHOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE; LATE LECTURER IN MORBID ANATOMY, VICTORIA UNIVERSITY OF MANCHESTER.

MOST of those who have had recent experience of the post mortem work of the Manchester Royal Infirmary have formed an impression that the incidence of intrathoracic tumours there is high. This has led to the suggestion that air pollution, which is exceptionally great in Manchester, may be a factor in the production of these tumours. In various other centres, both in Europe and in America, recent investigations [1] have made it appear that the incidence has increased in late years, and it has been thought that a similar increase was noticeable in Manchester. In order to ascertain so far as possible the actual state of affairs it was decided to make an investigation and analysis of all the cases which have been entered in the autopsy registers at the Infirmary up to the end of the year 1926. With regard to the problem of air pollution no satisfactory conclusion can be arrived at until the figures thus obtained can be compared with those from a number of other towns where there is more or less atmospheric purity, and it is with a view to arousing interest in the subject in other centres, so that investigations along similar lines may be carried out, that these findings are now being published. In this research it has been possible to study a large number of cases, and since it is only by the examination of large numbers, where numerous comparisons can be made, that many of the difficulties in differential diagnosis are made manifest, it has been thought permissible to discuss some of these difficulties for the guidance of those who may have less material on which to base their conclusions.

Incidence.

Registers of all autopsies performed at the Manchester Royal Infirmary since the year 1868 have been kept and, with the exception of the volume containing the medical autopsies of the year 1910, all are available for reference. These records have been carefully searched and every case where tumour-growth of the thorax was reported has been noted and considered. From amongst them have been chosen only those cases in which the evidence was conclusively in favour of their being primary intrathoracic malignant growths.

The first recorded case occurred in the year 1871, and in the years following, till the end of 1926, 175 cases have been discovered, as is shown in Table I.

TABLE I.

Years.	Post-mortems	Cases and percentage.
Up to the end of 1885	2107	5 (0·24)
1886–1890	1014	16 (1·58)
1891–1895	1175	15 (1·28)
1896–1900	991	12 (1·21)
1901–1905	1083	26 (2·40)
1906–1910	898	12 (1·34)
1911–1915	1141	27 (2·37)
1916–1920	910	22 (2·42)
1921–1925	1126	29 (2·57)
1926	335	11

It must be admitted that conclusions drawn from statistics of the cases which come to autopsy at a teaching school are open to criticism, for there must always be a tendency, in choosing cases for post-mortem examination, to choose those which have unusual features and to press more urgently for permission to examine such cases. Thus the pathological conditions which are most common in man are not those most commonly revealed in the post-mortem room. With the use of X rays as a method of diagnosis the recognition of tumours in the thorax is simplified, and it is probable that many cases which, 30 or 40 years ago, would have been passed as cases of pulmonary consumption are now recognised as of neoplastic nature, and are therefore deemed more valuable for the purpose of pathological instruction. Similarly in the admission of cases to a general hospital there must often be a certain amount of selection, because it is so frequently necessary to choose from amongst a waiting list only such cases as will most certainly benefit by hospital treatment. Nevertheless, when a large number of cases, gathered from a period extending over several years, can be examined, much may be learned regarding the tendencies of a pathological condition, and, in considering the figures in Table I., the slight increase in the percentage of cases cannot be disregarded. Although this increase is perhaps less than may have been anticipated, it is an appreciable one, and it seems permissible, even in view of the above-mentioned sources of error, to conclude that it indicates a true increase in the incidence of the disease.

In order to show how these figures in Table I. compare with the case-incidence in the hospital wards, Dr. E. M. Brockbank has kindly furnished the information given in Table II.

TABLE II.—*Numbers of Intrathoracic Neoplasms in the Wards during the Last Six Years.*

In 1925 ..	.. 27	in 2657 cases.
1924 ..	.. 20	„ 2656 „
1923 ..	.. 21	„ 2679 „
1922 ..	.. 27	„ 2677 „
1921 ..	.. 26	„ 2904 „
1920 ..	.. 27	„ 2821 „
	148	16,394 = approx. 0·9 %.

The fact that the percentage in the ward records tends to be lower than in the autopsy records seems to show that these latter are in no wise an accurate representation of the general incidence of the tumours. The high percentage in the autopsy records is probably in great measure due to the fatal nature of the disease.

The selection of true cases of primary intrathoracic tumours was difficult and was open to error. In only 78 of them did the material for histological examination still exist and without such material and with no more information than is furnished by a sometimes very brief post-mortem report, it was frequently impossible to be sure of the nature of a case. For instance, it was sometimes difficult to determine the site of a primary growth in a case where tumour nodules were numerous and widespread throughout the body. One such case, where enlargement of the mediastinal glands and infiltration of the lungs were present along with tumour masses in both kidneys, showed a microscopic appearance which corresponded so closely to that of a typical renal cancer that it was decided to discard it in spite of the fact that it had been classified as a mediastinal tumour. Again there was difficulty in eliminating with certainty all cases which were not of true neoplastic nature. In this respect Hodgkin's disease gave rise to serious difficulty. There appears to be no certain method, other than microscopic examination, of distinguishing lymphadenoma of the mediastinal glands from tumours arising at the root of the lungs. Lymphadenoma is capable not only of causing enormous enlargement of these glands, but also of penetrating deeply into the lungs and bronchi, giving rise to ulceration, obstruction, and suppurative bronchiectasis, so that it may simulate in almost every respect a bronchial cancer. Unfortunately the difficulty is not always removed by microscopic examination, since, at some early stages in the progress of the disease the tissues may in parts appear so highly cellular as to resemble a small or mixed cell sarcoma, and it is only the recognition of the large, lymphadenoma cell that renders the diagnosis certain,

* This research was carried out under the auspices of the Manchester Cancer Committee.

[1] A bibliography of recent papers will be found in the appendix to this paper.

This point cannot be too strongly emphasised, for there is much evidence to show that confusion in respect of these cases has existed in the past, even after microscopic examination has been made. In dealing with the cases where no histological material was available, the feature which was considered to be most strongly indicative of Hodgkin's disease was the presence of secondary nodules in the spleen, and accordingly all such cases (of which there were five) were discarded. This measure is not altogether satisfactory because, on the one hand, cases of Hodgkin's disease may at an early stage show no involvement of the spleen, and, on the other hand, secondary growths in the spleen, although perhaps uncommon in cases of primary tumour of the thorax, may sometimes be found, as was shown by one case in the collection. It was, however, considered best in the choice of the cases to impose restrictions calculated to cause under-estimation rather than over-estimation of the numbers.

Age- and Sex-Incidence.

The figures in Table III. are for the most part in agreement with the findings of other observers.

TABLE III.

In 175 cases { 151 were males = 86·29 %
24 „ females = 13·71 %

In 173 cases where the age of the individual was given :—

27	„ „ 41–45	1	„ „ 71–75

Occupational Incidence.

A record of the occupation of the individual was traced in 143 of the male cases. The largest number in any single occupation was found amongst labourers, and of these there were 28. Next to them in order of numbers came carters, of whom there were 9, and next to these clerks, numbering 8. In none of the other occupations were more than four cases recorded. It was found on counting the labourers in the former class that the outdoor and indoor workers were in nearly equal proportion, there being 72 outdoor to 71 indoor workers. The number of men who had described themselves as carters was striking, and this drew attention to those who registered occupations closely related in one way or another to that of carter. These total 25, and are set forth in the following list :—

Carters, 9; van drivers, 2; lorryman, 1; coachman, 1; teamster, 1; horse keepers, 2; ostler, 1; stableman, 1; tram drivers, 3; engine drivers, 2; tram guard, 1; railway guard, 1.

These represented all the transport workers in the list, so that such workers constituted 16·55 per cent. of all male cases.

With the help of a census list kindly supplied by Dr. W. S. McClure, of the Department of Public Health, Manchester, it was possible to compare the percentage of tumour cases in the various occupations with the percentage of the whole male population of Manchester in these occupations. It was found impossible to estimate with accuracy the numbers of outdoor and indoor workers, because many of the occupations specified in the list included workers in both these classes, but it could be judged that at least 75 per cent. of the adult population were indoor workers. Since, therefore, in the cases of tumour there were actually more outdoor workers than indoor ones, it may be concluded that the incidence is higher in the former class in a proportion of three to one. In the census list it was found that the transport workers constituted 12·34 per cent. of the total male population, whereas in the case list these workers, as stated above, constituted 16·55 per cent. of the male cases. In none of the other occupations were the numbers of cases large enough to allow of useful comparisons being made.

Morbid Anatomy.

In most of the cases the tumour was described as being large, filling the mediastina and involving one or other of the lungs, but it was frequently impossible from the description to determine whether the involvement consisted of a direct spread of the tumour into the lung or of a deposit in the lung of metastatic nodules. In two it was described as being situated in the anterior mediastinum, and one of these was reported to be a malignant tumour of the thymus. In our experience the smaller growths are usually seen to be situated in the walls of one or other of the main bronchi, near the bifurcation of the trachea. In practically all cases the neighbouring glands are affected, and it is frequently found that one or two of these glands, which can be recognised by their anthracotic pigment, are embedded in the growth and appear to form the centre of it. The spread into the lungs seems most frequently to be directed upwards to the upper lobes. A few secondary nodules in addition to the primary growth are frequently seen in the affected lung, but they are much less commonly found in the lung of the opposite side.

TABLE IV.—*Frequency with which the Lungs were Affected.*

Right lung	78 cases.
Left „	67 „
Both lungs	18 „
No lung involved	12 „

Although in these records the right lung was more often affected, necrosis and gangrene was more often noted in the left. Necrotic and suppurating cavities in the left lung were reported in 30 cases, and in the right lung in only 21 cases. Certain authors have explained the formation of these cavities as being the result of necrosis and breaking down of tumour nodules with the escape of their contents into the bronchi, but it is often easy to demonstrate in the post-mortem room that they are of the nature of infective bronchiectatic cavities, resulting from ulceration and obstruction of the larger bronchi at the site of the primary tumour. It would seem, therefore, that whereas the right side is more commonly infiltrated by tumour, the left side is on the whole more liable to suppuration; the left bronchus being more frequently obstructed. Although in many of the older cases ulceration of the bronchi has not been reported, it has been present in practically every case within our experience.

Other thoracic organs which may be invaded by the tumour growth include the pericardium, the œsophagus, and the superior vena cava.

Classification.

Only those cases in which histological material is still available are discussed in this section. In a great number of the earlier cases no report of a microscopical examination was made, and in these almost invariably the diagnosis made at the sectio was that of lympho-sarcoma of the mediastinum. Similarly the cases on which there were microscopic reports were most frequently found to have been classified as lympho-sarcomata, and it appears to have been customary to classify them as such, not so much from their micro-scopic appearance as from the fact that they were situated in the mediastinum. Since, as will be shown, lymphosarcoma is in reality a rare occurrence in the mediastinum, it was decided to disregard, for purposes of classification, all microscopic reports.

Material from 78 cases in the collection was examined histologically. Since the purpose of this paper is simply to give a statistical account of the incidence of intrathoracic tumours, an exhaustive description of their histology would be out of place here, and only

such summary of the features of the different main groups as will explain our method of classification will be given. With but 10 exceptions the whole 78 were included in the following two groups.

Group I. comprises the more or less typical and long recognised carcinomas of the bronchi. These include two different types: first, the large spheroidal or polygonal-celled alveolar type; and, secondly, the squamous or epidermoid type. In the first the structure and cells of the tumour usually bear some resemblance to the bronchial mucous membrane or to the mucus-secreting glands of the bronchi (Fig. 1), so that their recognition in view of their situation and macroscopic appearance is usually easy. In the second type the epithelial cells show metaplasia to a squamous form such as may frequently be seen in the epithelium of chronically inflamed bronchi, with the result that the tumours (Fig. 2) somewhat resemble epitheliomata of the buccal mucosa. They are composed of irregular masses of polygonal and spindle-shaped cells with deeply staining nuclei. The former cells are frequently arranged roughly in columns along the borders of the masses in the manner of the basal layer of the rete mucosum of Malpighi, whilst the spindle cells lie internally, often forming a whorl converging towards the centre of the mass. In a small number of cases cell-nests develop in these whorls, but prickle cells have not been shown in any of the cases.

Group II., with seven exceptions, consists of tumours which are now commonly described as oat-cell tumours of the mediastinum. The true classification of these growths is not finally decided, but there is a growing opinion that they are, as W. G. Barnard [2] has recently suggested, of the nature of medullary cancers of the bronchi. As will be shown, there is much evidence in the present material to support this opinion, notwithstanding the fact that the general microscopic appearance of many of them has undoubtedly in the past led to their being classified as lymphosarcomata, and thus to lymphosarcoma being considered a common tumour of the mediastinum. If one may take the structure of the lymphosarcoma to be that described by Ewing [3] and by other authorities—namely, a structure composed of lymphoid cells enmeshed in a delicate reticulum, such as is to be seen in malignant tumours of lymph glands in other parts of the body—it will readily be appreciated that these oat-cell tumours have no claim to such a classification. In them the cells, although they are usually small, may show a variation in size ranging from that of a small lymphocyte to that of the cells of the squamous type in Group I. They are characteristically oval or spindle-shaped (oat cells), though there is much variation in their degree of elongation, and they contain relatively large, darkly staining ovoid nuclei. They are arranged in solid masses surrounded by a framework of irregular bands of connective tissue wherein lie the blood-vessels of the tumour (Figs. 3, 4, 5, 6). In some the connective tissue is very plentiful, covering large areas, so that a considerable proportion of the tumour is fibrous (Fig. 6). In the cell masses there is a complete absence of intercellular reticular tissue and of capillaries, the tissue being dependent for its vascular supply on the vessels of the connective tissue bands. In the small cell variety (Figs. 3 and 4) the cells are sometimes rounded and less elongated, and may thus resemble lymphoid cells. The seven exceptions mentioned above are approximately of this type. They are tumours composed of small round cells (Fig. 7), and although all of them contain a few spindle cells, especially at the margins of the cell masses, these cells are not numerous and prominent enough to permit of the descriptive term "oat cell" being applied to the tumours. In every other respect, however, these cases conform to the type under discussion, and it seems most reasonable to classify them along with this second group. In the small-celled type the cells are frequently loosely arranged and form large masses which sometimes cover two or more fields of the microscope and are interrupted only here and there by sparse connective tissue strands. Sometimes these strands are little larger than the vessels they support, so that the latter appear to be isolated and in close contact with the tumour cells, when the likeness to a sarcoma may be considerable. In such places the cells are sometimes seen to radiate out from the vessels as in a perithelial sarcoma, but closer examination always reveals that these vessels, unlike those of a sarcoma, are stout-walled and possess an adventitial fibrous coat which represents the connective tissue framework of the tumour. In the large-celled variety (Figs. 5 and 6) the cells tend to be more closely packed and to form numerous small clumps. They tend also at parts to be more elongated and sometimes to form bundles and whorls, while at the margins of the masses column formation may be seen. In such tumours there may be a distinct resemblance to basal cell cancers, and in a few the cells at the centre of the mass may be seen to have fused and become hyaline, so that structures resembling cell-nests are formed (Fig. 8), making it appear that the relationship of these oat-cell tumours to the squamous tumours of the bronchi is very close.

In this second group structural variations too numerous to describe are found, and it is realised that many observers may not favour the inclusion of all the different types in the single class. Nevertheless, although there is wide variation in the structures, even the most remotely divergent cases appear to be inked together by a series of intermediate types which makes it difficult to see where any division in the classification could be made.

In the compilation of the group certain standards to which all the cases admitted have had to conform have been set. These are as follows: 1. The tumour cells form masses embedded in a framework of connective tissue which constitutes part of the tumour growth and is not merely a pre-existing tissue which has become invaded by tumour. 2. The vessels of the tumour are contained in the connective tissue framework and do not penetrate the cell masses. 3. The tumour cells are devoid of intercellular tissue.

These are standards which are applicable to true carcinomata and not to sarcomata or lymphomata, and while the small cell varieties may show histologically very little superficial resemblance to the usual conception of cancer, the fact that they conform to these standards, coupled with the fact that they seem closely related to other types which show a very remarkable resemblance to familiar cancers, seems to justify the classification of all these tumours as epithelial growths.

The similarity of the macroscopic appearance of the tumours of the different groups in no wise lessens the justification, for although the small oat-cell group tends to form larger and softer growths than, perhaps, does the tumour of the squamous type, the same may be said of the large spheroidal cell cancer. Indeed, it has been found repeatedly that the type of tumour cannot be determined from the naked-eye examination alone. All types arise about the roots of the lungs, infiltrate the bronchi, and cause enlargement of the mediastinal glands.

TABLE VI.—*Indicating the Number of Cases Contained in the Foregoing Groups along with the Average Age of the Cases in each Type of New Growth.*

	Type.	Number of cases.	Average age in years.
Group I.	Large-celled alveolar type	16	51·12
	Squamous celled type	13	46·61
Group II.	Oat-celled type	32	43·28
	Small round-celled exceptions	7	49·83

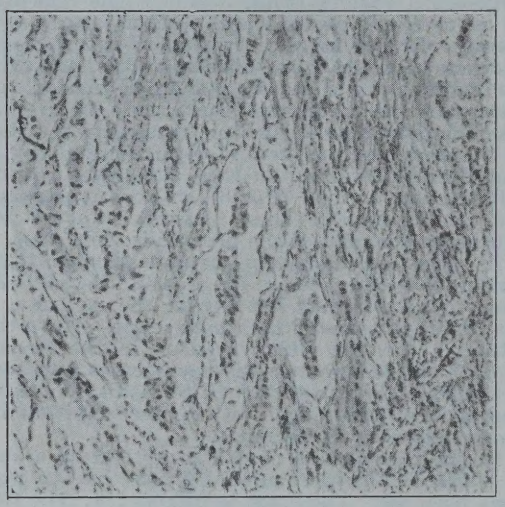
Exceptional Cases.

The following is a list of the cases which do not fall into either of the two foregoing groups. Notable amongst them are cases Nos. 1, 3, 4, and 8. These are tumours composed of spindle cells arranged in intertwining bundles. They are as a rule devoid of inter-

[2] Barnard: Jour. Path. and Bact., 1926, xxix., 241.
[3] Ewing: Neoplastic Diseases, 1919.

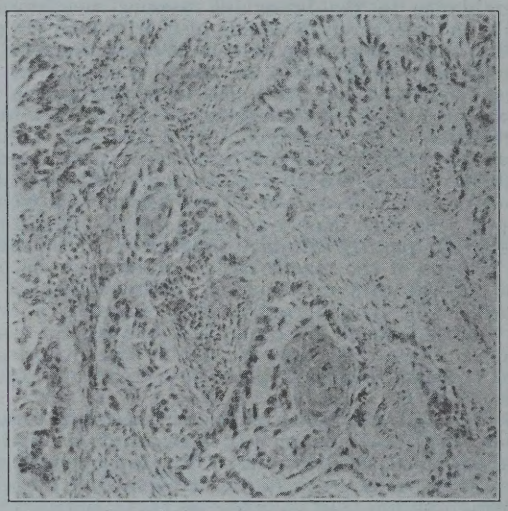
cellular tissue and the cells are of somewhat epithelioid type; some of them showing a slight resemblance to squamous cells, but the fact that the blood-vessels are very numerous and thin-walled prevents their being classified as epitheliomata. Their structure is one which is associated with growths of the pleura and, by some, they are considered to be of endothelial origin. As will be seen, in three of these four cases the pleura was especially mentioned as being affected.

FIG. 1.



A large-celled alveolar cancer showing a structure suggestive of an origin in the bronchial secretory glands. (× 120.)

FIG. 2.



A squamous cell tumour of bronchus showing cell-nest formation. (× 120.)

CASE 1 (22/510).†—Male, aged 36. Reported September, 1922, as "an endothelioma of both lungs." The tumour is composed of large, closely-packed spindle cells, some of which are irregular, branching, and almost syncytial.

CASE 2 (9274).—Male, aged 39. Reported August, 1918, as "a large tumour of the mediastinum with secondary nodules in right lung." Microscopically, a chondrosarcoma.

CASE 3 (8413).—Male, aged 41. Reported May, 1915 as "endothelioma of both pleuræ." A tumour composed of rather loosely arranged large spindle cells.

CASE 4 (8226).—Female, aged 31. Reported June, 1914, as "a tumour of possible thymic origin, involving left pleura and lung and invading pericardium." It is composed of large spindle cells amongst which there are a few polymorphic giant cells.

CASE 5 (8176).—Male, aged 26. Reported March, 1914, as "a tumour of mediastinum invading right lung, with metastases in abdominal lymph glands, adrenals, and bones." It is composed of small round cells amongst which there is a fine network of thin-walled capillaries and connective tissue fibrils. A possible lymphosarcoma.

CASE 6 (7699).—Male, aged 35. Reported September, 1912, as "a tumour of mediastinum invading left lung, bronchus, pericardium, and œsophagus." It is composed o small spindle cells amongst which there is a fine ramificatio of thin-walled capillaries. Although this case does no conform to the standards of Group II., the appearance of th cells suggests an epithelial type closely related to the sma oat-cell tumours.

CASE 7 (6176).—Male, aged 58. Reported May, 1909, a "a malignant growth of pleura." It is composed of rathe irregular, large, loosely arranged spindle cells. Some of thes

FIG. 3.

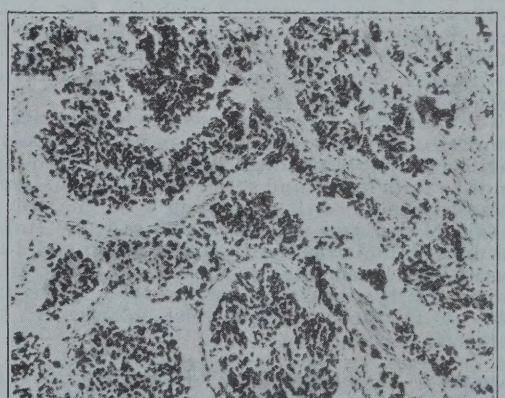


FIG. 4.

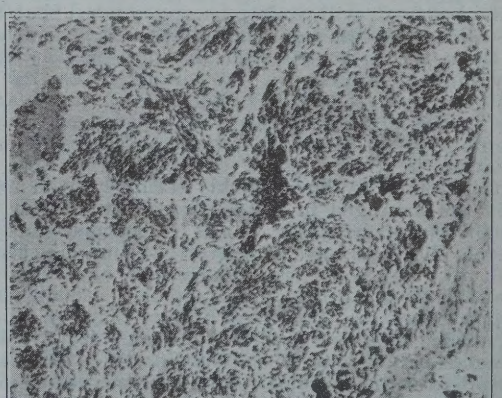


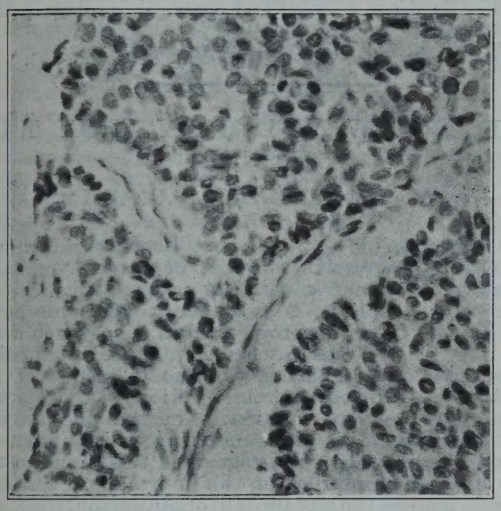
Small oat-celled tumours; the smaller celled tumour (Fig. 4) showing a larger cell mass. (× 120.)

† The case-numbers given in parentheses are those of the Manchester University pathological department day book.

appear to have branching processes so that there is a fine reticular appearance. The vessels are numerous and thin-walled. A tumour of very uncertain type.

CASE 8 (4140–1).—Male, aged 39. Reported September, 1903, as "endothelioma of left pleura with secondary nodules in liver and peritoneum." It is composed of large spindle cells arranged in whorl formation.

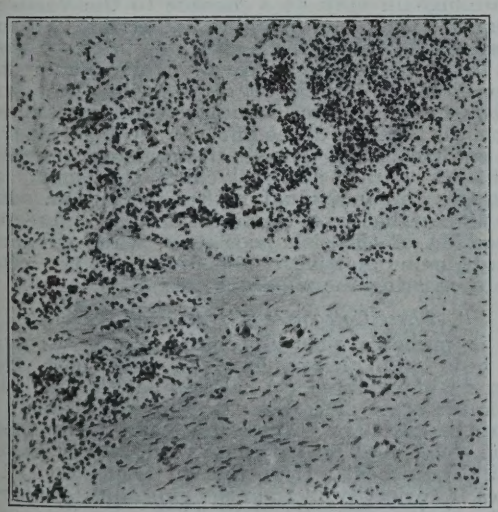
FIG. 5.



An oat-celled tumour with cells considerably larger than those of Figs. 3 and 4, showing the closer packing of the cells and the arrangement in columns at the margins of the cell masses. (× 300.)

CASE 9 (4139).—Male, aged 36. Reported September, 1903, as "a sarcoma of thymus not involving lungs." It is composed of closely-packed medium-sized, round cells. Only one section, which was stained in the year 1903, and which is in somewhat poor preservation, is available, so that an accurate description of the histology cannot be given.

FIG. 7.



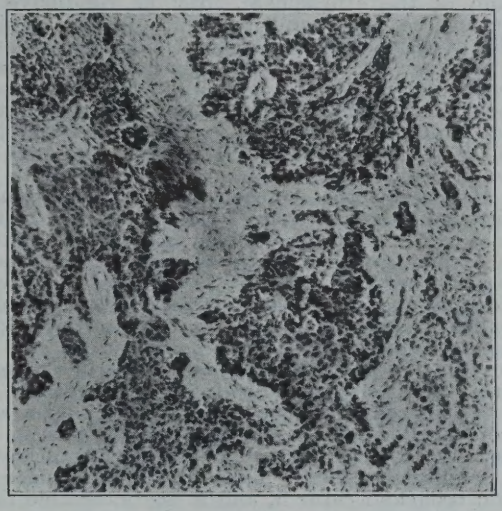
A small round-celled tumour in which the cell arrangement corresponds to that of the oat-celled tumours. (× 120.)

CASE 10 (1139).—Male, aged 26. Reported September, 1890 as "a mediastinal tumour invading left bronchus." It appears to be composed of large spindle cells like those of cases 22/510 and 8226. The only available section was stained in the year 1890 and is in a poor state of preservation, so that it is not possible to make sure of the classification in this case.

Discussion.

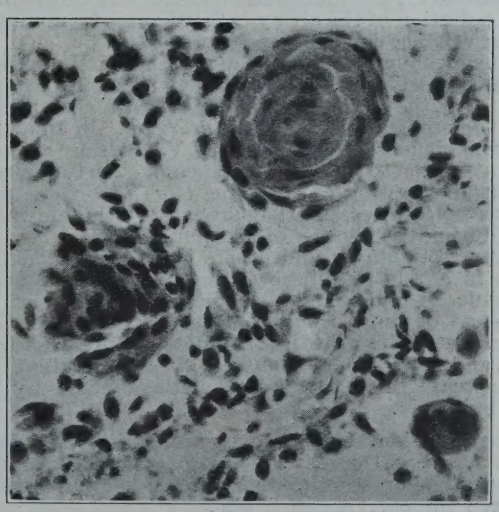
The value of these findings depends much on the question of the correct classification of the oat-cell tumours, or more especially on the question of whether or not they are tumours of the bronchi. If they are in reality bronchial cancers the findings would be the more valuable since it would then be shown that the bronchi, and not the mediastinal glands, are by far the most important structures in regard to tumour growths of the thorax. In Manchester bronchial cancers, instead of constituting only about 37 per cent. of thoracic tumours, would constitute considerably over 80 per cent. of these. The single fact that so many of the tumours arise in a tissue which is directly exposed to the atmosphere would encourage the suspicion that atmospheric impurity may be an important factor in their causation. Nevertheless it

FIG. 6.



A large oat-celled tumour; the structure in parts closely resembles that of the squamous tumours of the bronchi. (× 120.)

FIG. 8.



A medium sized oat-celled tumour in which the cells are undergoing a change like that of cell-nest formation in the squamous tumour. (× 500.)

must be some specific constituent of the pollution rather than the general atmospheric pollution itself that should be suspected, because the atmospheric conditions in cities are generally supposed to be improved since the coming into operation of the Smoke Abatement Acts, and were it simply a matter of a smoke-laden atmosphere, the incidence of thoracic tumours would be expected correspondingly to be on the decrease. There is strong evidence from elsewhere that special external conditions, probably through the medium of the atmosphere, may be conducive to cancer of the lungs and bronchi. In the mining district of Schneeberg, in Saxony, it has been shown that the men who work amongst ores of cobalt, bismuth, and nickel are especially subject to these tumours. Arnstein notes that one third of all the miners admitted to hospital in that district in the years 1907–11 were admitted with a diagnosis of pulmonary cancer.

In Manchester the figures point to no particular industry as being dangerous in this respect, but rather to those who are outdoor workers as being more prone to thoracic tumours than those who work in more sheltered conditions. It has been noted, however, that carters and drivers are comparatively numerous in the list of those affected. Obviously no conclusions can safely be drawn from such findings alone and all that can be done is to cite briefly some possible reasons for men of that class being so frequently affected.

In the first place, men who work in the open and are constantly exposed to weather conditions in an excessively damp climate such as that of Manchester may possibly be unduly exposed to the danger of chronic bronchial catarrh, and it is conceivable that such irritation may be a factor in the production of bronchial cancer; full enough information regarding the past histories of the cases to settle this point cannot now be obtained. In the second place, men who are much on the roads are exposed to an atmosphere which is very often heavily laden with dust and particles of most varied materials, and it may be that materials of a similar nature to those responsible for the high incidence of cancer among the Schneeberg miners may also be present in road dust. A relationship between cancer of the lungs and conditions of the highways has been suggested by other observers. Staehelin has suggested that the modern custom of tarring roads is responsible for the increased incidence and others have cited pollution of the air by exhaust gases from motor-driven vehicles as being a possible factor.

Thus although the figures derived from Manchester are in themselves insignificant, they are of importance in so far as they yield evidence which is in concurrence with the propositions of other observers. In an article on Branchiogenetic Carcinoma, R. V. Hudson [4] recently drew attention to the high incidence of such tumours in grooms, suggesting at the same time that these men are susceptible because they are liable to inhale much dust during the process of grooming horses.

Myer,[5] Berblinger, and others have considered that there is a relationship between the great influenza epidemic of 1918 and the recent increase in the incidence of lung cancers. Staehelin, however, has shown that the increase in Basle dates from earlier than 1918, and from the figures herein given it is patent that the increase in Manchester is little affected by the 1918 epidemic.

In conclusion, I wish to express my gratitude to Prof. J. Shaw Dunn, who first proposed the undertaking of this research, for his much help and advice towards the carrying of it out.

A POOR-LAW INFIRMARY FROM THE INSIDE.

BY F. J. O'DONNELL, F.R.C.P. IREL.

IT is impossible to work in a Poor-law infirmary, where the progressive changes of recent years are operative, without constantly speculating on its future as a hospital. Almost every day some event calls attention to the problem, and I have set down here impressions formed when I was resident medical officer at a large infirmary. The existence of the problem is admitted, but its solution is a subject of sharp divergence of opinion. On the one hand a purely negative attitude, emanating mainly from the voluntary hospitals, encourages the traditional ostracism and unpopularity of the infirmary. Such an attitude ignores the advances in organisation, tone, and equipment made in certain infirmaries within recent years, the implications of a State examination for nurses, and the tentative efforts, now some years on trial, to find a wider field of utility for such institutions.

On the other hand, a more enlightened outlook thinks that the infirmary could be more extensively utilised in the general campaign against disease. The antagonism to the progressive outlook, which is the only logical sequel to the labours which have brought the infirmary to its present stage of development, is difficult to understand.

It is true that reorganisation on the lines adopted in Birmingham may be a menace to the voluntary system, but it is questionable whether this particular scheme, even if feasible, is either desirable or would meet with universal approval. Inherent in it is obviously the danger of reproducing the whole problem in a new form. The problem is not merely to turn the facilities of the infirmary to better advantage, but to eliminate from its atmosphere that element which, its critics claim, "chills the soul" and submerges the individual in the institution. It is easy to see that over-classification and subsequent segregation of the sick poor may, while advancing towards one objective, be defeated at the other, thereby marring the whole process of approach.

Three Categories of Infirmary Patient.

It is probable that any large infirmary of say 700 beds will always have to deal with three categories of patients: (*a*) helpless patients, including inoperable cases of cancer; (*b*) the semi-invalids for whom the infirmary is the Cannes and Bournemouth of the rich; and (*c*) patients specifically in need of hospital treatment. If preventive medicine in all its phases is to justify in time the expenditure incurred on it, that justification should be nowhere more apparent than in a fall of the demands at present made on infirmary accommodation by types (*a*) and (*b*). As regards (*c*) it is admitted that the voluntary hospitals are congested, and that reasonably well-equipped infirmaries are only partially utilised. There is room here for coöperation between the two systems, without the slightest risk to the voluntary principle.

Envisaging then the infirmary as a unit in the hospital system, it is natural to inquire why it is still

regarded with suspicion and antipathy, and it will be apparent from such an analysis that the infirmary at present is handicapped by various anomalies, which nullify in great measure all efforts towards progress.

Although the statutory disabilities of admission to an infirmary may now be regarded as void, the mode of admission in conformance with Poor-law regulations is illogical since the advent of the panel system. Given a semi-State medical service, such as the panel system, it seems to me inconsistent for its staff not to be entitled to send patients in need of hospital treatment direct to a State-supported hospital without the intervention of another official—parish doctor or relieving officer. The panel system and the infirmary should be ancillary one to the other, and if this relationship is to be utilised to the utmost, intercommunication must be free and devoid of all unnecessary officialdom. The intrusion of the parish doctor between patients and their private doctors serves no useful purpose; it is a handicap on the scope of the infirmary and should be eliminated. Such a step should go far to allay the prejudice excited by the present procedure, while it should not be difficult at the same time to safeguard the interests of the guardians.

Abuse of Infirmary Beds.

While recognising how wide its net should be, one must admit that the present easy access to the infirmary is open to abuse. The transfer there from other hospitals of cases "gone wrong" or only partially treated, of patients from the local mental hospital on a month's probation (a procedure, I believe, without the slightest legal basis), of patients in the last stage of illness sent in to die—these are examples of abuse. Clearly in such cases the infirmary is regarded as a dumping-ground and is discredited accordingly.

Of the numerous functions devolving on the infirmary, none are more damaging to its reputation than the mental wards and the arrangements for advanced tuberculosis. Somehow these entities constitute for a large section of the community a miniature of the infirmary as a whole. The Poor-law mental ward is a travesty of the more humane outlook accorded of recent years to mental affliction, and, as such, its serious consideration is overdue. The presence in the infirmary of advanced tuberculous patients, however isolated, is apt to be regarded as a menace by the public—a very intelligible prejudice. There can be no doubt that the infirmary will have to shed these anomalous elements before much headway towards winning public confidence can be made.

The infirmary is also handicapped, both internally and externally, by its ill-defined status. Internally, although the guardians as a body may be enthusiastic on the development of the active side of the infirmary, there is an undercurrent of semi-official opinion distinctly sceptical about the capacity of the infirmary to become a progressive hospital force—a legacy no doubt of long association with the Poor-law. Externally, this handicap is expressed in the comparative failure of the infirmary, as a hospital, to carry the confidence of the public and the medical profession.

Lack of Coöperation.

The lack of coöperation between the infirmary and the outside medical world is also remarkable. The amount of acute illness treated within the year is considerable, the surgery done there is not negligible, the panel patients coming to the infirmary are numerous, and yet very rarely indeed is there any communication between the staff of the infirmary and the outside doctors. As far as my own experience goes what happens in the infirmary seems to count so little that even a brief history on admission and a brief report of progress on departure are dispensed with. Cases of difficult labour are received at the infirmary without any details of their history, or of what had been attempted outside in the way of treatment.

Again it has come within my experience that a large number of rheumatic children may be treated in the infirmary for months on end, but when the time comes for their discharge there seems, amidst the whole expensive maze of preventive medicine, no individual unit whose duty it is to take over their future supervision. School medical officers no doubt come across these children later on, but never once, in my three and a half years' experience, did an inquiry reach the infirmary about such children, well over a hundred in number. It was apparent, therefore, that the infirmary was isolated in its activities and regarded as something apart from other efforts to combat disease and promote public health, and that this isolation accentuated the tendencies, inherent in all institutional life, towards a constricted outlook and a loss of personality—tendencies which it is highly desirable to eradicate. If the infirmary is to realise in any measure the hopes some have for its future, its present isolation must be broken down and it must be brought out into the currents of medical thought and activities.

There can be no doubt, for example, that a superintendent who lives apart from the infirmary stands a better chance of preserving a fresh outlook and runs less risk of losing his personality than does his resident confrère. If he is allowed some outside practice, he is less likely to lose the individual in the patient—the great temptation of exclusive institutional work. Similarly with the nursing staff of the infirmary; the more they see and know of other hospitals, the broader will be their outlook and the better their own work. More potent than any other factor in the removal of this spirit of isolation from the infirmary will be a greater scope for thorough and conclusive work with a growing outside recognition of its merit.

Infirmary and Workhouse.

No discussion of the future of the infirmary would be complete without some mention of the influence upon it of the workhouse proper, where the two are adjacent. The system probably handicaps the infirmary, but against this has to be placed the economy of administration which the system allows, and the increased resources thereby available for its development. The workhouse (a name which should certainly be abolished) consists of two sections—one for the aged, which is really quite a creditable home for old people, the other for the healthy. In the latter, humanising influences seem to have come up against a dead-end, the personal factor seems to have defied solution, and the hard traditional atmosphere of the Poor-law remains. The proximity of this relic of the past is a danger to the future of the infirmary, and its amelioration is worthy of serious thought.

Some reference must also be made to a rather prevalent professional opinion which thinks that the infirmary has no contribution to make to medical progress. How wide of the truth is such an opinion is demonstrated by the success of Savill's "Clinical Medicine," written from what its author called "the great unexplored mine of clinical medicine." Only a profound ignorance could be blind to the facilities which a modern infirmary offers for wide post-graduate study. Perhaps also as a stage of end-results not merely of individuals, but of a profession and its science as a whole, the infirmary is worthy of a passing note. These end-results are secluded, and therefore forgotten, but they represent in no small measure the toll which preventable disease still takes of the community.

In conclusion, I would suggest that the future of an infirmary, where the progressive changes of recent years are operative, lies between remaining a semi-penal social necessity or developing into a genuine social asset, and that for such an infirmary, with certain of its existing handicaps removed, with its activities rendered more homogeneous, with a more definite outlook and status, perhaps with a change of name, the more optimistic alternative is certainly logical and probably feasible.

GUMMATOUS ADENITIS IN CONGENITAL SYPHILIS.

WITH NOTES OF A CASE.

BY JAMES H. SEQUEIRA, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,
CONSULTING PHYSICIAN TO THE SKIN DEPARTMENT, LONDON HOSPITAL;
AND
JOHN T. INGRAM, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, EVELINA HOSPITAL; LATE PATHOLOGIST, ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN; AND FIRST ASSISTANT, SKIN DEPARTMENT, LONDON HOSPITAL.

ONE of the least common of the tissues to be affected by syphilis in its later manifestations is the lymph-adenoid tissue of the body. Gummatous lesions of the lymph glands or of the spleen are extremely rare,

Gummatous ulceration and adenitis of the neck.

and Fournier,[1] in a review of over 2000 cases of late syphilitic lesions, does not mention the condition.

During the period of infection and while that infection is being overcome, by time and medication, the subject acquires an increasing sensitivity to the invading organism, and, we believe, gummata constitute the reaction of such a hypersensitive subject to residual spirochætes. That being the case it is not to be expected that the spirochæte, a fragile organism, should linger in tissues of high phagocytic power as the lymphatic tissues. Further, the anatomical structure of the lymphatic gland does not lend itself to the sequelæ of endarteritis and thrombosis which are essential features of gummatous lesions elsewhere, a fact which may in part account for the atypical histological appearances of gummatous lesions in the glands when they occur.

Probably the earliest reference to gummatous adenitis was published by Potier [2] in 1842 under the title of Affection Cancereuse des Ganglions Inguinaux. The case was that of a woman, aged 68, who had contracted syphilis four years previously and who subsequently developed an indolent swelling of glands of groin. The clinical description of the case suggests that it was one of gumma. Wile,[3] in 1912, recorded a case of gummatous adenitis, confirmed by demonstration of spirochætes from the lesion. In reviewing the literature he estimated that there were under 100 cases on record. Barth and Gomboult [4] reported one case of gummatous cervical glands associated with gumma of the thyroid; the diagnosis was confirmed by biopsy. Coues [5] reported four cases in 1915 and a further case in 1922; three of these were congenital syphilitics. Hughes [10] reported a case in 1925 almost identical with our own in every particular. Recently in a paper on cases of unrecognised congenital syphilis, Goldhurst [6] reported seven cases of glands of neck, some of which were broken down, with positive Wassermann reactions. The rapid response to antisyphilitic treatment confirmed the suspicion that they were gummatous in nature.

The association, therefore, of gummatous adenitis and congenital syphilis is well established, but it is sufficiently uncommon to merit the report of the following case:—

A girl, aged 11, was seen in the Light Department of the London Hospital in March, 1927, with gross cervical adenitis. In September, 1925, the child was alleged to have had tuberculous glands of neck while under treatment for phlyctenular ulceration of both corneæ. From July, 1926, to January, 1927, she received tuberculin injections at intervals of about ten days. Under this treatment the eye condition cleared, but the glands gradually increased in size. She was then admitted to a surgical ward and a gland excised for section, the pathological report being: "Caseous and granulomatous areas in cervical lymph gland; possibly syphilitic or tuberculous or Hodgkin's granuloma. No tubercle bacilli seen."

In March the child presented massive bilateral cervical adenitis with a gummatous mass about one and a half inches in diameter on the right side of the neck posteriorly. This mass and ulcer had the characteristics of a tertiary syphilitic lesion, as seen in the accompanying illustration. The blood Wassermann reactions of the mother and of the child were both positive, that of the father being negative.

There were no other stigmata of congenital syphilis except well-marked Hutchinson's incisor teeth; there was no deafness and the eyes, both as regards corneæ and fundi, were clear. There was, however, a marked wasting of thenar and hypothenar eminences of both hands with a tendency to claw-hand, a condition which had been present as long as the mother could remember, and was described as double-jointedness. Cerebro-spinal fluid obtained by lumbar puncture showed a negative Wassermann reaction, an absence of cells, and no excess of protein. The lesion here is probably the result of an old syphilitic meningovascular lesion in the region of the anterior spinal roots of the first thoracic nerves.

Treatment started on March 10th with mercurial inunctions was continued on March 17th by intravenous injections of novarsenobillon, 0·45 g. repeated at weekly intervals. Unfortunately, after the fourth injection the child developed chicken-pox, but at this time the glands were subsiding and the gummatous ulcer was healing.

When seen recently the patient was convalescing from the specific fever. The glands were about half their original size, and the ulcer, which had almost healed, contained a small slough. Treatment will be resumed as soon as the child is allowed to attend hospital.

This case was, in our opinion, one of gummatous cervical adenitis associated with congenital syphilis. Whether or not there was also tuberculous infection of the glands affected it is difficult to state. Cornil,[7] Lowenbach,[8] and Fasal [9] all emphasise the fact that the histopathology of the lesions in gummatous lymphadenitis is not typical of syphilis. In our own case biopsy gave similar evidence—namely, that of an atypical granulomatous inflammation.

AN X RAY PIONEER.—As President of St. Thomas's Hospital the Duke of Connaught has presented the Carnegie Hero Medal to Mr. Chisholm Williams in recognition of his services to radiology. Mr. Williams was so seriously affected by the nature of his employment that he is now no longer able to follow it. During the war he did good work for the ex-Service men in the Bristol area of the Ministry of Pensions.

Clinical and Laboratory Notes.

TWO CASES OF FOREIGN BODY REMOVED AFTER TEN YEARS.

BY E. H. R. ALTOUNYAN, *M.C.*, M.D. CAMB.,
ASSISTANT SURGEON, THE ALTOUNYAN HOSPITAL, ALEPPO, SYRIA.

THE foreign bodies removed were (1) a bullet in the lung and (2) a coin in the nose.

Bullet in the Lung.

History and Physical Signs.—A Kurdish man, aged 30, presented himself at the Altounyan Hospital suffering from profuse intermittent hæmoptysis of two months' duration. He stated that he had been wounded at Gallipoli during the war in the right arm and chest. Apart from a brisk initial hæmoptysis he had suffered no great inconvenience, though he had been invalided out of the army shortly afterwards. Two months before admission, while doing some heavy manual work, he had had a very copious hæmorrhage. Since then he had lost much blood.

Although the patient himself was convinced that hæmorrhage came from the right lung, and was caused by the bullet, a careful physical examination gave no clue. A radiogram showed a bullet in the right base, surrounded by an ill-defined opaque area, but the right apex did not appear quite clear. It was necessary, therefore, to try to exclude tuberculosis. The sputum was examined on five different occasions with a negative result.

It was proposed to induce an artificial pneumothorax on the right side, and to attempt extraction of the bullet through a Chevalier Jackson bronchoscope. It was felt that an artificial pneumothorax would reveal any existing pleural adhesions which was a point of considerable importance, in view of the possibility of an external operation; whilst bronchoscopy would at any rate definitely show from which side the blood was coming.

Artificial Pneumothorax.—Accordingly Dr. A. Poche (in charge of the artificial pneumothorax clinic) between Feb. 8th and 15th, 1926, injected, at two-day intervals, 300, 400, 600, and 550 c.cm. of air, the final pressures reading $-12+1$, $-7+3$. On Feb. 16th a radiogram showed considerable collapse of the lung, and the absence of adhesions in the region of the bullet. The hæmoptysis continued unabated. The blood count showed red cells, 3,680,000; white cells, 7500; hæmoglobin, 37 per cent.

First Operation.—On Feb. 20th the patient was prepared for bronchoscopy by Chevalier Jackson's method. After the third application of cocaine to the pharynx there was a very profuse hæmorrhage; over a pint of froth and clot was expectorated. It was decided to proceed at once by the external route. Under novocaine anæsthesia the seventh rib was resected for a distance of 15 cm. forwards from the anterior axillary line. On incising the air-distended pleura, and opening it widely with retractors, there was no alteration in the patient's quiet breathing. The collapsed lung, lying against the mediastinum, was seized with a Duval forceps and drawn into the wound. It was impossible to palpate the bullet. The presenting lung was then sutured into the wound and packed with gauze for adhesions to form.

Second Operation.—On Feb. 25th, after radioscopic localisation, needles were passed through the lung tissue but failed to touch the bullet. It was decided to remove the bullet under the X ray screen. Without anæsthesia, either general or local, the presenting lung was freely incised and the bullet removed with a long stone forceps. This was a very difficult and somewhat desperate procedure. The patient was coughing up blood very freely and the respiratory movements were much exaggerated; during the manipulations the newly formed adhesions were broken down and the reopening of the pleura produced a very embarrassing dyspnœa and mediastinal flutter. Eventually the lung was seized, drawn out, and sutured once more to the wound. Normal respiration was immediately restored, and from this time on no further hæmorrhage occurred.

During the operation it was ascertained that the bullet moved freely in a sac of lung tissue. Hæmorrhage was apparently caused by the bullet repeatedly injuring blood-vessels in its walls. It is difficult to see why the artificial pneumothorax proved so powerless to influence the loss of blood.

Twelve hours after operation the patient's condition was one of extreme distress; the pulse-rate was 160, the respirations 56, and the temperature 97·2° F. On removing the dressings it was found that a progressive pneumothorax was being produced through a pin-hole opening in the suture line. This highly dangerous condition was finally controlled by a gauze pad soaked in paraffin, held in place and made air-tight by suturing the skin carefully over it. By the next morning the pulse-rate was 120, the respirations 40, and the temperature 102° F.; the patient was safe. On Feb. 28th a large collection of septic fluid was evacuated from the pleura. The cavity was packed with gauze and air was excluded as much as possible.

Third Operation (March 4th).—There was now a large septic cavity between the lung and the diaphragm. The free movement of the diaphragm, which was plainly visible, obviously rendered the eventual healing of the wound problematic. Accordingly a right phrenicotomy was performed under novocaine anæsthesia, and the cavity was subsequently treated by continuous permanganate irrigation.

On March 23rd the patient left hospital, at his own request, with a large granulating wound. The diaphragm, practically immobile, could still be distinguished. The radiogram taken at this time shows large air spaces and collapsed lung. The patient reported six months later in good health. There had been no further hæmorrhage; there was a small fistula at the site of the wound. An X ray examination was refused—perhaps not unnaturally.

The following comments may be made: (1) In the light of after events it would obviously have been preferable to have boldly incised the lung at the first operation and removed the bullet. This was not done in the hope of avoiding the danger of infecting the pleura. (2) The ineffectual localisation of the bullet was due to its mobility in the sac. (3) Phrenicotomy should have been performed earlier, possibly at the first operation.

Coin in the Nose.

A man, aged 20, complained of right-sided headache and running from the nose of about one year's duration. The Wassermann reaction was negative. Examination of the nose revealed a mucous discharge from the right side, and on transillumination the right antrum was found to be opaque. Puncture of the antrum gave clear washings. After three weeks' observation a radiogram showed an opaque body in the inferior meatus of the right nares. A second careful examination with the nasal speculum failed to reveal a foreign body. Finally, after localisation, a nasal forceps was introduced under the right inferior turbinate and slowly advanced into the mucous membrane; a small silver one-piastre coin, measuring 1·5 cm. in diameter, was extracted. There was a brisk hæmorrhage. When confronted with the coin, the patient was able to recall that, when a small boy, he had at one time been in the habit of entertaining his friends by producing coins from his mouth, which he had previously introduced through his nose. He had no recollection of any coin sticking.

The radiogram shows considerable thickening of the nasal wall of the right antrum and broadening of the right inferior meatus. As so often happens, there was little in the history to suggest a specific search for a foreign body. The headache still continues, though the nasal discharge has ceased. The serum reaction of the blood for tubercle (Besredka's antigen) is strongly positive.

A NOTE ON TOTAL AND DIFFERENTIAL CELL COUNTS IN CEREBRO-SPINAL FLUID.

BY C. E. NEWMAN, M.B. CAMB., M.R.C.P. LOND.,
MEDICAL REGISTRAR, KING'S COLLEGE HOSPITAL, LONDON.

PATHOLOGISTS are faced with two difficulties in counting cells in cerebro-spinal fluid: (1) It is sometimes very hard to differentiate between lymphocytes and red blood corpuscles (even the most expert have been known to make mistakes); and (2) stained films have a lamentable tendency to wash off the slide. The following method obviates both these difficulties, and has the additional advantages of being much more accurate and taking much less time.

A capillary pipette is drawn out and a grease pencil mark is made about an inch from the end. Into this are sucked with a rubber teat a volume of cerebro-spinal fluid, an air-lock, and a volume of 1 in 300 brilliant cresyl blue solution in normal saline. The contents are well-mixed by blowing out on to a slide, and a drop is put up on a counting chamber. The leucocytes will be found to be beautifully stained, while the red corpuscles are unaltered.

The total count is thus very easy, and at the same time a differential count can be done, because lympho-

cytes, polymorphs, ependymal cells, and even plasma cells can easily be recognised under the sixth inch objective. The count is more accurate than that done by the stained film method, because there is no tendency for the cells to be selectively dragged to one end of the film. The method has been in use for two years in this hospital, and has proved perfectly reliable.

Medical Societies.

MATERNITY AND INFANT WELFARE.

NATIONAL CONFERENCE IN LONDON, JULY 5TH–8TH.

THIS conference was, as we noted last week, of the usual wide scope and attended by delegates from all parts of the country. In his opening address as President of the conference Mr. NEVILLE CHAMBERLAIN dwelt on the triple partnership between the Ministry of Health, the statutory health authorities, and the voluntary health associations in welfare work. During the three crowded days which followed two of the most interesting discussions were on wet nursing and the provision of sick nursing in the home for children under school age.

Wet Nursing.

Dr. CATHERINE CHISHOLM (Manchester) described the system in operation at the Manchester Babies' Hospital since 1922. At first there were two mothers with their babies in residence. Now owing to successful results there are three. The mothers receive 10*s.* a week and all found. The good condition of their own baby encourages them. They are not allowed to leave the grounds except for a special reason. During five and a quarter years 24 have been in residence. Everything is done to secure healthy foster-mothers by medical and dental examinations (including the Wassermann test). The *real* baby is not entirely breast-fed, but has first call on its mother's milk. The foster-baby is not suckled, the milk being either expressed by hand or drawn off by a hand-pump or Abt's electric pump. The largest amount of milk given in the day has been 105 oz. Promiscuous suckling is revolting to some mothers, and the milk may "go" in consequence. Also the foster-child, if suckled, might infect the foster-mother. Dr. Chisholm claimed that the system has been of incalculable value to premature infants, and instanced a baby of 1 lb. 5 oz. weight on admission who did well. Sometimes the breast milk is diluted or peptonised.

Dr. RONALD CARTER (London) had made use of wet nursing 30 or 40 times in 20 years at his welfare centres. He took great care to select healthy mothers, rejected any who had had miscarriages or stillbirths, &c., but did not use the Wassermann test. He was also not impressed with the effect of oral sepsis, if it did not affect the general health. He had taught the mothers how to express the milk at home from one breast while their baby was suckling the other and to collect it and bring it up to the centre under clean conditions. In the selection of foster-mothers the health visitor's knowledge of the home circumstances was a great asset. The difficulty of organisation and transport was an obstacle to the spread of the system. Occasionally he had got a woman to actually suckle the baby of a neighbour or relative. During the last year he had obtained breast milk from the maternity department for cases of marasmus in the children's wards of St. Mary Abbot's Hospital and also from the borough council maternity department for other marasmic babies, and he believed a considerable supply could be obtained from similar institutions. He thought there should be centres in every area for the supply of breast milk, but was "not altogether in favour of the woman being paid for her milk."

Dr. HAROLD WALLER (London) referred to the unsavoury history of wet nursing in past centuries. As a voluntary act the supplying of milk for an alien baby was highly meritorious, but the sale of the milk did not seem a pleasant idea. At St. Katharine's, Poplar, they used the excess milk only, the *real* baby being entirely breast-fed. Few mothers had the temperament for suckling alien babies, but many mothers had so much milk that it was difficult for their own baby to suckle and much easier when some of the excess milk had been expressed. He always had the excess breast milk boiled before giving it to another baby. He thought the Wassermann test should be insisted upon, that the foster-mother's teeth should be in a sound state, and that it was better to have the milk expressed at the centres.

Dr. BRAID BIRKS (Salford) said lying-in mothers often had too much milk, and Dr. S. G. MOORE raised the point of the difference between the fore milk and the after milk, and the need for seeing that the *real* baby got its fair share of cream.

Councillor MARGARET BEAVAN (Liverpool) claimed good results from a similar system at the Liverpool Babies' Hospital, where they paid the foster-mothers 20*s.* a week as compared with Manchester's 10*s.*

Dr. MARGARET EMSLIE described a scheme which was being inaugurated in London for the regular expression, collection, and transport of human milk. The existence of centres and health visitors in all areas had made such a scheme possible.

Mrs. MCGHIE (St. Helens) pointed out that the mothers did the suckling of alien babies among themselves and asked if they were going to try to regulate such voluntary schemes.

Another speaker suggested that one could hardly pay for mother's milk, but one might pay her for the time, trouble, and work involved. A woman Poor-law guardian of 30 years' standing feared that the baby suckled by an alien mother might acquire her mental qualities and habits. The trend of the discussion was distinctly favourable to the extension of the system with proper safeguards for securing healthy foster-mothers and the well-being of the foster-mother's own child.

Nursing of Young Children at Home.

Miss E. HALDANE, who took the chair for the "nursing in the homes" discussion, referred to the great need for this service and also to the great improvement in education of young mothers as compared with the past.

Miss J. R. WATTS (Q.V.J. Institute for Nurses) put the case for a unified system of home nursing and dealt with the financial difficulties, which had prevented the Institute from training enough nurses. Most of her work had been done in Scotland, in the crowded industrial areas in which there was now a great demand for nurses on the provident system, which they were unable to meet. The medical profession as a whole had not properly backed the establishment of district nursing and might have secured nursing as one of the benefits of the Insurance Act if they had insisted. Miss Watts spoke quite impartially and did not attempt to dictate whether the service should be provided by statutory authorities or a subsidised voluntary association.

Dr. J. E. SPENCE (M.O.H., Eccles) described the system in Eccles, designed to prevent overlapping. The districts there are compact, with no long distances to cover, and the duties of health visitor, school nurse, and of home nursing of the children are carried out by one woman. Instead of an area with 400 annual births, the Ministry's standard, each of these health nurses has an area with 180 births. This system has worked well for four years in Eccles.

Some of the points which emerged from the discussion were:—

1. At the present time health visitors with districts of "400 births" cannot supervise the toddlers, much less do sick nursing. To be called upon for sick nursing usually means neglect of the health visitor's proper important duties.

2. There should be one home nursing service, controlled in each area by one body. Before the ideal is obtained, the

subsidies to nursing associations should be increased and better coöperation with the preventive service might be secured if the M.O.H. or his deputy were a member of the management committee of the district nursing associations in his area.

3. The education of girls in sick nursing before marriage was put forward as an effective way of diminishing the need for home nursing. A miner's wife, the mother of nine children, described how owing to some training in first-aid she was able to nurse her ninth child herself, when it was badly burnt. She paid a woman to help with the household work in the meantime.

Dr. ETHEL CASSIE (Birmingham) said the aid of a home-help often enabled the mother to use the skilled nursing of the school clinic, when she could not otherwise have done so. Better housing would act both ways. It would lead to fewer cases of sickness needing nursing but it would permit many cases of respiratory disease, which have to be removed to hospital at present from an impossible environment, to be nursed at home.

Milk-borne Tuberculosis.

Dr. A. STANLEY GRIFFITHS (University of Cambridge Field Laboratories) in an evening lecture on the pasteurisation of milk in relation to surgical tuberculosis, said that there was no difficulty in distinguishing between the bovine and human strains. A tuberculous udder might give 100,000 tubercle bacilli to 1 c.cm. of milk. Milk might contain tubercle bacilli without the udder showing signs. The fæces were the second greatest infector of milk because most of the lung tubercle bacilli were swallowed. Even if tuberculous udders and emaciated and advanced cases were excluded from milk herds, the raw milk would not be safe. The doctrine that bovine tuberculosis was a useful immuniser against human tuberculosis was a very dangerous one. The bovine type might affect any organ and cause death by meningitis, general tuberculosis, and ulcerative pulmonary tuberculosis, although owing to the alimentary system being its usual portal of entry it was rarely the cause of pulmonary tuberculosis. It was a mistake to think that it was a mild form of the disease. An estimate founded on examination of material from the living and from post-mortems showed that 6·9 per cent. of the deaths from tuberculosis were from the bovine type. This meant that there were 3000 deaths in England and Wales during 1924 from tubercle-infected milk, and this figure was probably an underestimate because the post-mortems did not include those of children under 2—a very susceptible age.

The Tuberculosis Order had not, he said, as yet produced much effect. His examination of 19 cultures from fatal cases during 1926 and 1927 showed that eight were of the bovine type, and most of the large cities had a higher percentage of tuberculous milk in 1926 than in 1925. The percentages for Birmingham, Manchester, Leeds, and Edinburgh were 9·4, 10·3, 10·4, and 11·0 respectively. To make raw milk safe they must gradually get rid of reactors and build up tubercle-free herds. Dr. Griffiths gave some figures from Guernsey. From 1910–19, 2426 animals were tested with tuberculin and 191 reactors found. Recently 2882 had been tested and only two animals reacted.

Infant Mortality.

Dr. A. S. M. MACGREGOR (M.O.H., Glasgow) opened a discussion on respiratory diseases as a factor in infant mortality. He referred to the excessive infant mortality from both respiratory diseases and diarrhœa in the north and expressed the opinion that the cause for the difference between north and south was to be found rather in industrialism and poverty than in difference of climate. He gave statistics for Glasgow showing that the mortality from respiratory diseases was the chief single cause of the difference in the infant mortality-rates in the industrial and poor wards of the city as compared with the residential wards. He advocated a close research study of child life conditions in the areas around the various welfare centres. Rickets increased the mortality from these diseases. Glasgow was regarded as the home of rickets, but there had been a remarkable decrease in rickets during the last 20 years. Glasgow had for years adopted the policy of providing hospital accommodation for measles and whooping-cough which so frequently had respiratory complications.

Dr. CHODAK GREGORY dealt with the treatment of pneumonia. Out of 100 cases, 40 might be of the lobar type. Lobar pneumonia in childhood was not so serious and had a case fatality of about 12 per cent., whereas broncho-pneumonia had a case fatality of 50 per cent. Lobar pneumonia could be more easily treated at home but was more frequently sent to hospital than broncho-pneumonia. The fear of its being due to an infectious disease (e.g., measles) often delayed the admission of broncho-pneumonia. Early diagnosis was therefore important. Hospital construction was unsatisfactory. Large wards were difficult to heat and ventilate and gave no facilities for isolation. She recommended groups of small wards. Our climate was hardly suitable for actual open-air treatment but the bed should be at the open window.

Dr. K. SIMPSON (M.O.H., Barking) dealt with bottle-feeding, rickets, malnutrition, and tuberculosis as predisposing causes of broncho-pneumonia, and expressed his approval of the action of the M.A.B. in making hospital provision for broncho-pneumonia complicating measles and whooping-cough.

Other items of interest included a survey of the working of the Maternity and Child Welfare Act, 1918, by Dr. F. E. Fremantle, M.P., addresses on the practical teaching of mothercraft (Dr. Mabel Brodie), on the blessing of sunlight and the curse of smoke (Dr. Leonard Hill and Dr. C. W. Saleeby), and on the provision of observation wards and hospital beds for infants and children under school age (Dr. James A. Stephen, Aberdeen). The fourth day of the conference was given up to tours in practical illustration of subjects discussed.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

THIRTEENTH ANNUAL CONFERENCE.

(*Concluded from p. 69.*)

HOUSING: HOME CONDITIONS.

IN the absence through illness of Dr. H. R. KENWOOD (professor of hygiene in the University of London) his paper was read by Dr. A. M. HEWAT (senior medical officer, L.C.C.). Prof. Kenwood had no doubt that complete measures for the prevention of tuberculosis could now be formulated, but they would be held to be prohibitive as to cost, in spite of the heavy economic waste from a disease which after three or four years of sickness destroyed life at the rate of 7000 to 8000 per week in England and Wales. But more of the money already provided for special measures of direct attack should be spent upon preventive measures apart from the cure of the patient. They needed to adopt a wider outlook upon prevention by regarding all members of the infected family as definitely subject to a risk. When a notification was received and a family was found in which the disease had appeared, the really essential thing was to find out why that particular family unit had "fallen by the way," and then to do all that was possible to prevent any extension of the disease in that susceptible family. Certain points, he thought, should be borne prominently in mind. From the early days of the voluntary notification of pulmonary tuberculosis, and for many years subsequent to the compulsory notification of the disease, he visited every notified case in Stoke Newington, and he was always impressed with two facts—that notifications mostly came too late, and that it was often impossible to secure such satisfactory home and living conditions as would be likely to provide a really useful measure of protection against any extension of disease in the home, especially when

young children were present. There was always some adverse factor which could not be removed, and most commonly the major evils of bad air in the bedroom and bad nutrition were in association. In more recent years there had been some improvement in these respects, but even now much had to be left undone or done to a partial and therefore often futile extent. It was certain that without good notification they could not get good results from direct measures. Taking at random an annual report for 1926 of a large town, he found there were 275 deaths from pulmonary tuberculosis; of these 22 were dead when first notified, 145 were dead within 12 months, and 36 were never notified. In another town over 55 per cent. of the notified cases were dead within six months. Such unsatisfactory notification largely explained the ineffectiveness of direct measures against tuberculosis. In childhood both prevention and cure were of special importance, and it was there that both problems assumed the most simple and economical dimensions. The important preventive measure of boarding out children who were running a risk of infection in tuberculous homes had not been as generally adopted in this country as it should have been. There was no doubt in his mind that a large amount of excellent institutional work was almost wasted from the lack of efficient after-care work, and he also doubted whether this latter would be fairly generally provided until its essential importance, when performed as it should be, was more fully appreciated. He held the view very strongly that suitably trained whole-time officials were needed for this work, and that a detailed national scheme of after-care should be framed and enforced. Better sanitary and social conditions were increasing the people's resistance to the disease, and the risks from a massive dosage of infection were diminishing, but the advanced case in most poor-class homes remained a standing menace to the health of some of its occupants, and a limited amount of segregation, optional or compulsory, should be more generally demanded.

Discussion.

Sir WILLIAM YOUNGER (Member of the Royal Commission on Housing for Scotland, and chairman of Dumfries and Galloway Sanatorium) gave a number of instances of cases of tuberculosis which had occurred owing to badly built and dirty houses. The problem of bad homes must be solved if any progress was to be made. He urged the establishment of convalescent homes for children under the same authority as the sanatorium, where children with known bad homes could go after treatment in a sanatorium and remain until they were in a state of health to face their home conditions.

Sir WILLIAM THOMPSON (late Registrar-General for Ireland) stated that the death-rate from all forms of tuberculosis in the Irish Free State per 100,000 of the estimated population, as represented by the number of deaths registered, was in 1906, 253·1; in 1916, 210·9; in 1926, 146·8. The corresponding rates for pulmonary tuberculosis were respectively 193·8, 168·2, and 113·4. Some of the decrease, he felt sure, was due to better housing conditions, at any rate in the rural areas.

Dr. F. J. H. COUTTS (Ministry of Health) referred to the importance of propaganda work in educating the public, not only in the sense of instruction, but also in encouraging them in the study of health matters.

Dr. H. DE C. WOODCOCK (Leeds) urged that more serious attention should be given to the consideration of trades in regard to the treatment of tuberculosis.

On Friday, July 1st, Dr. E. L. COLLIS (Mansel Talbot Professor of Preventive Medicine, University of Wales) delivered an address on

HOUSING AND INDUSTRIAL CONDITIONS.

Statistically, he said, they were aware that the mortality from tuberculosis had been falling steadily and regularly for more than 50 years. In the 13 years that had elapsed since the National Association last discussed the prevention of tuberculosis from the viewpoint of the home and the factory two statistical periods were represented. The first was the war period, during which mortality from pulmonary tuberculosis rose, the rise being confined to the ages 15 to 30 years. In this country the rise was particularly investigated for women, and was shown to be in direct proportion to the extent to which they were called upon to perform munition work. The second was the post-war period, during which the trend of the pre-war fall was resumed, affecting chiefly the ages 15 to 30 years. This fall occurred while overcrowding, due to inadequate housing, was at its height, and apparently had been in no way affected for better or for worse by amelioration in the housing position. Unhygienic environment appeared, as far as tuberculosis was concerned, to be of far less importance than malnutrition.

The position seemed to be that there was a ubiquitous endemic infection. In infancy it carried off those who had inherited no resisting power; in early adult life it carried off those whose resisting power was lowered either by impaired digestive powers or by a dietary inadequate for their needs; in middle life it carried off those for whom the wear and tear of early adult life had been heavy. The two latter groups were particularly represented in occupational life. Heavy work on entering industry and low pay, entailing an inadequate dietary, predisposed to the disease in early adult life. Industrial life for most women terminated with marriage, while for men it continued throughout life. The pronounced difference, then, which existed between the mortality from tuberculosis of males in middle life and that of females might reasonably be ascribed to industrial conditions. To-day the stronghold of tuberculosis when estimated by the mortality from phthisis at age-periods per 1000 living was found among males of middle age in industrial districts; but mortality at this period of life might reasonably be held to represent the cumulative effect of industrial life as lived during the last 30 years. The effect of the shorter hours of work customary to-day would only become manifest as years passed by. When they reviewed the fall in phthisis mortality since 1860 it was found to have been most pronounced in infancy, at that period of life when infection was the only factor at work, and to have been least pronounced in middle age, when infection was greatly aided by wear and tear. The conclusion presented was that the amount of tuberculous infection had been diminishing; it might still be ubiquitous, but it was less intensive. The point where the enemy was weakest lay in the control of infection. The method for following up their advantage was clear. They must recognise that tuberculosis was infectious; they must recognise the tubercle carrier, just as they did the typhoid carrier; they must eliminate the infected from their factory industries and place them in industrial colonies; they must continually impress upon the public the infectious nature of tuberculosis. Finally, when, as the incidence of the disease continued to fall, sanatorium accommodation was sufficient for housing and treating all the remaining cases, strict segregation must be adopted. Not until they controlled the infection would the disease be finally eliminated.

Sir THOMAS OLIVER (professor of medicine, Durham University) said that overcrowding was one of the greatest causes of illness, and especially of tuberculosis.

Mr. Councillor C. W. ALLISON (Stockton-on-Tees), in the course of the discussion, said that employers needed educating as to what was their duty towards the workers. In a new industry started in his district stone was first drilled by a wet process, but when customers objected to the moisture a dry drilling process was substituted, as a consequence of which the workers were likely to suffer from phthisis. The Chairman said that he would take the earliest opportunity of bringing the matter to the notice of the Ministry of Mines.

At the conclusion of the discussions visits were arranged to various institutions and housing schemes, including Preston Hall, L.C.C. housing schemes at Hammersmith, Burrow Hill Colony, Frimley, and Welwyn and Letchworth Garden Cities.

Reviews and Notices of Books.

THE SCIENCE AND PRACTICE OF SURGERY.

By W. H. C. ROMANIS, M.A., M.B., M.Ch. Cantab., F.R.C.S. Eng., F.R.S. Edin., Senior Surgeon in Charge of Out-Patients and Teacher of Practical Surgery, St. Thomas's Hospital; Surgeon to the City of London Hospital for Diseases of the Chest; and PHILIP H. MITCHINER, M.D., M.S. Lond., F.R.C.S. Eng., Surgeon in Charge of Out-Patients, Teacher of Operative Surgery and Demonstrator of Anatomy, St. Thomas's Hospital. London: J. and A. Churchill. 1927. Vol. I., 795 pages. Vol. II., 956 pages. 14s. each volume.

THE writing of a text-book of surgery for undergraduate students at the present day is a laborious undertaking. It requires a nice judgment in the selection of material, in the rejection of much that occupies the minds of progressive surgeons but is of a debatable nature, and particularly in the method of presentation to the reader. Above all things, the undergraduate must be taught facts and the general principles upon which surgery is based. Pure hypothesis and speculation, unless they are intrinsically necessary for the understanding of treatment, should be left for later study. It is, therefore, with these considerations in mind that such a text-book as that before us should be approached.

Vol. I. begins with general considerations. It describes the materials and chemicals used in surgery, their use and preparation, sterilisation, the pre- and post-operative treatment of patients. Inflammation and repair occupy a very few pages and this section, together with that on bacteriology, might almost have been omitted without much loss to the book. The general infections, syphilis, tetanus, anthrax, and so on are succinctly described and give the student in a short space all that he need know of these diseases. Indeed, that part of the subject usually included under the term general surgery is all well done. Thus the section on tumours describes the ordinary new growths met with by the surgeon, the most common sites of their origin, and gives an account of appropriate treatment, the whole section being adequate and yet not long enough to confuse the undergraduate student. Chapters on bone and joint diseases present short but clear summaries of a branch of surgery which always presents many difficulties to the beginner. On page 311 there is a slip in the formula for the normal reaction of nerves to the galvanic stimulus. The recent requirements of examining boards as to knowledge of X ray methods are met by a chapter written by Mr. Geoffrey Fildes.

Vol. II. is a treatise on regional surgery. Here again difficulties have been successfully overcome, particularly in the chapters on the surgery of the cranial contents. The management of head injuries conforms to modern practice, but there is no mention of that very useful instrument, the spinal manometer. Naturally the experienced reader turns soon to the section on exophthalmic goitre, a subject upon which one of the authors has done much work. Here we find the statements that spontaneous cure very rarely occurs, that medical treatment should be tried for some months, that failure to improve is very common, whilst operation is usually followed by excellent results. According to the authors rapidity of heart-rate and cardiac dilatation are not contra-indications to operation, but evidence that the heart is failing is a contra-indication. But what else is cardiac dilatation but evidence of overstrain of the heart and failure to maintain the circulation with intact walls? The authors do not practise ligations of thyroid vessels and avoid operation during the second six months of the disease. They do not mention the use of basal metabolic estimations in judging the effect of treatment or in deciding whether an operation is indicated. The abdominal section of the book is written on the usual lines and is good. Here and there individual opinion is very emphatically expressed, as, for example, in the treatment of appendicitis, but due acknowledgment of other views has been given. The remainder of this volume maintains the high standard set up in the first.

It would, of course, be easy for the specialist in any branch to criticise on the score of omission almost any section of the work. For instance, the stomatologist might expect, with some reason, a reference to the latest work which has been done on the treatment of carcinoma of the tongue with radium. But the authors have evidently considered this beyond the range of the book, and any but a very exacting critic will bow to their decision. If we regard the book as a whole it becomes obvious that the authors have got their values right. They present a well-balanced account of the science and art of surgery as practised at the present day. One very good feature is the inclusion of the specialties, including gynæcology so far as it concerns the general surgeon, and diseases of the eye, nose and throat, so that a student preparing for a pass examination in surgery need not buy a number of books dealing with its different branches. If he absorbs the information contained within the covers of these volumes he will certainly satisfy the examiners, and will, moreover, have acquired a very good basis of knowledge should he have ambitions for higher degrees in surgery. There was room for this text-book, and the authors are to be congratulated upon the production of a very useful and practical manual for the undergraduate student. The price is very moderate.

ANATOMY.

Lehrbuch der normalen Anatomie des Menschen. By Prof. Dr. F. SIEGLBAUER, University of Innsbruck. Berlin and Vienna: Urban and Schwarzenberg. 1926. Pp. 908. M.21.

HERE is an excellent book on formal anatomy, and this in spite of the absence of any figures or diagrams. Prof. Sieglbauer has foregone illustrations of set purpose, and even if we do not agree with all the reasons he gives for his decision, we must admit that he has produced a work which deserves cordial praise. He has well covered the ground necessary for the student, his descriptions are reliable, and his style of presenting the subject is interesting, simple, and concise. The author is evidently a Greek scholar and enthusiast, and brings the humanities to bear on his writings. Altogether this is a book of unusual merit.

Toldt's Anatomischer Atlas. Thirteenth edition. By Prof. Dr. FERDINAND HOCHSTETTER. In three vols. Berlin and Wien: Urban and Schwarzenberg. 1927. Pp. 984. M.36.60 and M.42.60.
Toldt's Atlas of Human Anatomy. Revised edition. Adapted to English and American and International Terminology. In two volumes. By EDEN PAUL, M.D., M.R.C.S., L.R.C.P. New York: The Macmillan Company. 1926. Pp. 985. 42s.

Toldt's Atlas is a classic in the anatomist's library, and it was with peculiar pleasure that we have received these two separate issues of the famous work. Prof. Hochstetter's edition, although it preserves practically all the old familiar figures, presents some new features in the shape of many excellent drawings, executed in the spirit of the original, while the addition of X ray photographs, associated with the areas under illustration, makes a valuable inclusion. Some new embryological figures are given; it is surprising to find that no advantage has been taken of the recent work on development of veins. We welcome this new edition of an old favourite.

The revised edition of Dr. Eden Paul's translation of the Atlas will also be welcomed by English-speaking students, because of the excellent notes and references introduced by the translator. It is refreshing to read these addenda. We have been rather drifting away from the old body of descriptive anatomy bequeathed to us by our fathers, or perhaps it might be said that, while working at its internal scope and

bearing, we have tended to take only a secondary interest in its outer boundaries and appearance, and notes such as these are good correctives to such want of attention. The two volumes ought to be in every anatomical library.

STOMACH DISORDERS.

A Handbook of Diseases of the Stomach. By STANLEY WYARD, M.D., M.R.C.P., Physician to the Bolingbroke Hospital. London: Humphrey Milford, Oxford University Press. 1927. Pp. 387. 16*s*.

THE main facts concerning disorders of the stomach are so well stated in this book that it should form a useful volume in any practitioner's library. Perusal of the sections dealing with hæmatemesis, gastric cancer, or the treatment of peptic ulcer is sufficient to disclose the wise judgment of the author, and the fact that he writes after deep reflection and much experience. We have, for instance, seldom read a more closely-reasoned account of the factors for and against the surgical treatment of gastric ulcer. The book may be criticised on the ground that the arrangement of the matter in the various chapters does not show strict logical sequence. Why, for instance, dyspepsia, hæmatemesis, and a heterogeneous assortment of symptoms called "conditions of unknown pathology" should form the three parts of Chapter VI. it is a little difficult to understand. And again, in a book which for obvious reasons omits description of cholecystitis and pancreatitis, the inclusion of sections on psittacosis and infantile diarrhœa is rather baffling. It would, however, be wrong to allow these defects of arrangement to disguise the excellence of a little book which is far better than many pretentious volumes dealing with the same subject.

The author at times allows his individual opinions some prominence, as when he defends imported meat on page 53, and condemns both liquid paraffin and bismuth in Chapter V. There is a seeming contradiction concerning pain in gastroptosis on page 172, and on page 347 an unfortunate transposition of the numbers referring to charts renders the text unintelligible. The numerous X ray illustrations, on the other hand, are beautifully clear and serve their purpose admirably.

TUBERCULOSIS OF THE MIDDLE EAR.

Das Problem der Mittelohrtuberkulose. By Dr. A. I. CEMACH. Berlin and Vienna: Urban and Schwarzenberg. 1926. Pp. 224. M.9.

Dr. Cemach has thoroughly examined a large number of cases of tuberculous disease of the ear with interesting results. He divides his cases into three groups. He examined the consumptive patients of an entire army corps, numbering 2342 (Group I.); among these he found 258 cases of aural suppuration, of which 63 were acute and 195 chronic; of the acute cases 5, and of the chronic cases 51, proved to be tuberculous. Classified according to the stage of the pulmonary disease, the results were: first stage, 716 cases, 7 with aural tuberculosis, or 1 per cent.; second stage, 1152 cases, 25 aural, or 2·1 per cent.; third stage, 474 cases, 24 aural, or 5 per cent. Among 1320 soldiers with apparently healthy lungs (Group II.) he found 59 cases of middle-ear suppuration, of which 3 proved to be tuberculous. Group III. consisted of 300 cases of aural suppuration among adults; of 81 acute cases, none were tuberculous, and of the remaining 219 chronic cases, 14, or 4·7 per cent. of the total, had tuberculosis of the ear. These details show the considerable number of cases dealt with; it is to be observed that they are all adults. Dr. Cemach deals exhaustively with the question of diagnosis; he considers a negative Pirquet reaction very valuable in the exclusion of tuberculosis in ear disease, but lays most stress on a positive focal reaction from subcutaneous injection of tuberculin, and claims that the method is only dangerous in acute and progressive cases. In the search for the tubercle bacillus he employs Petrov's method of cultivation on an egg-medium, using gentian violet to inhibit the growth of associated bacteria. As to treatment, the indications for operation are the same as in non-tuberculous suppuration; the author insists strongly on the value of tuberculin in skilful hands; he holds that this method of treatment should not be undertaken by the otologist, but by a specialist in tuberculosis working in conjunction with him. The author evidently holds strong opinions, which will not meet with universal acceptance, but he supports his arguments well; the book, although too verbose, provides plenty of material to interest other workers on tuberculosis as well as otologists.

ANIMAL NUTRITION AND VETERINARY DIETETICS.

By R. G. LINTON, M.R.C.V.S., Professor of Hygiene, Royal (Dick) Veterinary College, Edinburgh. Edinburgh: W. Green and Son. 1927. Pp. 399. 21*s*.

THIS book is a welcome addition to veterinary literature. It will help the students as well as the practitioner, since it brings all the essential facts connected with nutrition before them in one handy volume. Without a thorough knowledge of how animals are fed in health the veterinary surgeon cannot know how to feed them when they are ailing. The practical agriculturist also will find much to interest him. Prof. Linton has divided his subject-matter into six sections, of which the first deals with the composition and function of foods, the second with the foods, the third with their nutritive value, and the fourth with their preparation and storage. The last two sections are devoted to the feeding of cattle, horses, sheep, pigs, dogs, and poultry, and to the consideration of certain foods which are harmful. An appendix gives the weight of foods by measure, and the composition and nutritive value of foods. Here and there in the book one finds a little more information than the title would lead one to expect—for example, in the fifth section recommendations are given regarding the hygienic treatment of the new-born calf.

The book is almost entirely a plain statement of fact. Little controversial matter is included, and the reader will consequently find little to criticise, except perhaps it be the statement on page 43, that "evidence is constantly increasing which tends to show that many diseases of farm animals owe their origin to malnutrition." If the author had said "some" diseases, more of his readers would have been inclined to agree with him. Recent years have shown a tendency for some investigators to accept wholeheartedly the view that by feeding animals properly diseases will to a large extent disappear, just as another school holds to the view that diseases, even the dread foot-and-mouth disease, can be *bred* out of our flocks. Such views are worthy of careful and polite consideration, but their wholehearted acceptance is likely to lead to disappointment.

COLLOIDAL REACTIONS OF THE CEREBRO-SPINAL FLUID.

Les Nouvelles Méthodes sur les Réactions Colloidales du Liquide Céphalo-rachidien. By EUGENE DE THURZO. Paris: Maloine. 1927. Pp. 182.

THIS book contains full accounts of the well-known colloidal reactions of the cerebro-spinal fluid, such as the Lange colloidal gold reaction and the colloidal benzoin reaction. In addition to these standard methods a series of extraordinary reactions which are little known in this country is described and their diagnostic value discussed. These seem to us nebulous both with regard to their method of application and to the deductions made from the results obtained. A short bibliography is included after each chapter. The information contained in the volume is little more than that given in the ordinary text-books and manuals of practical pathological and laboratory diagnostic methods.

THE LANCET.

LONDON, SATURDAY, JULY 16, 1927.

CANCER OF THE LUNG.

DURING the last four or five years several pathologists in Europe and America have drawn attention to the fact that cancer of the lung has become substantially more frequent in their experience than it used to be. In our present issue Dr. J. B. DUGUID discusses the relevant data from the Manchester Royal Infirmary, and there is certainly an unpublished impression among the pathologists of several other British hospitals that they have observed a similar increase. When an attempt is made to translate this impression into the neat statistics which are so desirable a good many difficulties arise, and this perhaps explains why more has not been published on what seems to be an extremely interesting and important subject for cancer research to engage with.

There is, in the first place, the difficulty of clinical diagnosis. Intrathoracic tumours give rise to a variety of symptoms, which do not necessarily lead direct to a correct diagnosis. In large hospitals with skilled clinicians and adequate technical equipment the error is now probably small; in less specialised practice it is probably very considerable. In any case, death certificates could not be regarded as good enough for the details of the inquiry. In the second place, if the scope of the inquiry is limited to the data obtained at autopsies (and in fact it is from this source that the described increase has been identified), the nature of the tumour found is not altogether certain. Definite carcinomata of bronchi, either spheroidal or squamous-celled, constitute only a proportion of the cases under discussion. Commoner than either of these is the tumour known in the past as an "oat-celled sarcoma" and believed to originate in the mediastinal glands. Recent scrutiny, well described by Mr. W. G. BARNARD,[1] seems to show fairly conclusively that these growths are really carcinomata too. If that is so, most (though not all) of the "sarcoma of mediastinum" of the older records should be grouped as carcinoma of bronchus. And, thirdly, having verified the diagnosis by autopsy and agreed upon the nature of the tumour after microscopical examination, we are faced with the difficulty which is always present in any attempts to ascertain the real prevalence of a disease in time and place from its occurrence in the selected class which constitutes our hospital population. It is, we believe, very nearly impossible to obtain a precise comparison between any two hospitals, or between any two periods in the same hospital. The criteria of admission differ very widely and with the progress of medicine and surgery are constantly changing; an Addison or a Horsley on the staff may upset the statistics of an institution as seriously as do the available beds in proportion to the population, the presence of a medical school, or the standard of the local Poor-law infirmary. Recognising these difficulties, one has to express the figures as best one may: the percentage of cancers of the lung (or intrathoracic tumours) on the total admissions to the hospital, on the total autopsies made, on the total autopsies in which malignant disease was found. Dr. DUGUID uses the second method; several observers have used the third which is perhaps the least bad, but none is perfect.

Giving all the weight they deserve to these criticisms of any numerical measurement which may be made, there is, we believe, ample evidence that the statement "cancer of the lung is considerably commoner than it used to be" is true. There seems also to be no doubt that it is much more frequent in men than in women—i.e., that it is connected either with a male habit or with occupational rather than home life. Further than this it seems hardly possible to go at present; we hope that some of the cancer research organisations will take up the problem intensively, for it is evident that most important evidence can be obtained if the disease can be definitely traced to some mode of life. It should be possible to do this and various suggestive relationships have been put forward already. Dr. DUGUID finds that a remarkably large proportion of his cases were occupied in one way and another with road traffic; road traffic as a whole has, of course, enormously increased but the emanations from motors, including particles of oil, and the use of tar on the roads, are obvious possibilities. Experimentally, tar and other products of the combustion of coal have a unique carcinogenic efficacy, and Dr. A. N. KINGSBURY has recently attributed [2] a scrotal epithelioma in a Tamil to the irritation of oil sprayed in antimalarial operations. Tobacco-smoking is much more prevalent than it was, and it is one of the signs of the times that the class from which general hospital patients are mostly drawn have changed pipes for cigarettes. Dr. E. FROMMEL, in an interesting paper [3] on their experience in Geneva, attributes the greatest importance to a dusty occupation, and his data seem to show that vegetable dusts (as in woodmaking) are as important as mineral particles. It is well known that various inflammations will cause metaplasia of the bronchial mucosa to squamous epithelium. The suggestion has been made that the increase in pulmonary cancer is due to the 1918–19 epidemic of influenza. If that is so, there should later on be a corresponding decline in frequency. But while we wait for time to answer that particular question it is most desirable that a concerted attack should be made on the whole problem—the more so because it seems likely that it is in large part soluble. Dr. DUGUID'S tentative findings might justify a grant from the Road Fund for the purpose.

TWO CENTENARIES.

REFERENCES have been made in many places during the last year to the burden that is accumulating for our descendants through the modern habit of holding centenary celebrations, but no one will deny the perfect propriety shown by the authorities of Guy's Hospital when deciding to commemorate, in a full and dignified programme, the scientific work of that great son of their school, RICHARD BRIGHT. It was not the centenary of BRIGHT'S birth which was acclaimed last week, but that of the publication of the first volume of his "Medical Cases," the volume which contained the message which has proved of such signal importance to the world. The proceedings at Guy's Hospital formed an international testimony to BRIGHT'S fame. From the United States of America, from France and Germany, representative men of science came to add the voices

of their countries to the chorus of commendation, and from the many-sided eulogies there emerged a masterly picture of a great clinician. BRIGHT was simple in his objectives, undertook his investigations without prejudgment, had indefatigable industry, and, being neither precipitate nor vain, escaped the set-backs which attend the over-confident. He was a persistent critic of his own observations, and, though often he must have found that his accuracy had not been at fault, he continued to the end to apply to his latest collections of facts the same rigid testing which had led to his original discovery.

While centenary honours were being paid at Guy's Hospital and at the Royal College of Physicians of London to RICHARD BRIGHT'S genius, an address commemorating the services of LISTER was delivered at the Royal College of Surgeons of England by Prof. A. F. VON EISELSBERG, of Vienna. LISTER was only 6 years old when BRIGHT told the first consecutive story of the condition known as Bright's disease, and the reflection that must follow is, as Prof. THAYER pointed out in his oration at Guy's Hospital, that BRIGHT was remarkably early in employing scientific collaboration to the solution of clinical problems. His forerunners in medicine were isolated investigators whose success sprang from personal experience and personal experiment; the idea of team-work, which nowadays dictates the procedure of nearly all official and unofficial inquiries into disease, was hardly born, and the part that BRIGHT played in its introduction in itself stamps him as a pioneer of medical research. To-day the association of numerous talents furnishes the reason for the clinics of our teaching hospitals and is recognised as advantageous in every kind of investigation. But such an association is worthless for the study of disease unless it rests upon a basis of common belief; there must be an accepted conception of pathological processes. And LISTER'S pre-eminent gift to surgery lay in the provision of the unifying influence that his discoveries in relation to infection eventually exerted. They offered a new basis for research as well as for practice, and they made it possible for surgeons, united on the fundamental principles of infection, to direct their joint attention towards pathological problems beyond. The terms of reference of a research committee can be settled and the rôles of the members allotted in a way that 80 years ago was impossible; but RICHARD BRIGHT went very far in this procedure, and the greatest honour is due to him for his foresight and the modesty which underlay it.

Prof. EISELSBERG devoted part of his address to showing the extent to which this unity, promoted by LISTER, had enabled science to advance. The revolutions in technique had made possible BILLROTH'S successes in gastric surgery, HORSLEY'S work on cerebral localisation, and the study of endocrine disorders. Perhaps, he hinted, the ease of operative measures to-day sometimes tempted surgeons to excessive interference, against which it was necessary to guard at all times, and in this warning he called attention to some of the greatest difficulties which attend the work of the operating surgeon. Despite the possession of a fundamental basis of learning, and despite the high level of general teaching, there must be situations in which a given procedure will be a matter of routine for the man of great opportunities, or a legitimate invitation to the man of genius, while remaining hazardous for the less fortunately endowed. Some of Prof. EISELSBERG'S wise maxims on this and other aspects of the practice of surgery will be found in the report of his address published in this issue. Read together with Sir BERKELEY MOYNIHAN'S glowing tribute to the speaker they form an indication of Prof. EISELSBERG'S worthiness to receive the second award of the medal founded to perpetuate LISTER'S memory.

SCARLET FEVER.

Scarlet fever, though no longer the fatal and terrifying disease it once was in England, is still very common among us. During each year of the last decade some 80,000 cases have been notified on the average, and although the proportion of deaths has reached little more than 1 in 100, the interference with school education and with the daily life of the homes infected has been enormous, while a vast amount of public money has been expended no hospital isolation and treatment. The situation thus briefly indicated has induced the Ministry of Health to make an inquiry into the nature and efficacy of the measures at present carried out; materials furnished by the public health service and by fever hospital superintendents have been collected and analysed by Dr. A. C. PARSONS, and his report, which has just been issued,[1] contains the conclusions of a committee of medical officers of the Ministry on the main objects of the inquiry.

In his preface to the report Sir GEORGE NEWMAN recalls the three groups of problems presented by an infectious disease of wide prevalence. First, there is the cause, which in the case of scarlet fever is not yet fully ascertained. Then there is the problem of immunity, on which substantial progress has been made. Thirdly, there is the practical question of administration which cannot wait for the discovery of the cause or the solution of the problems of immunity. The present inquiry is concerned with administrative measures and the lessons to be drawn from their success or failure. In most parts of the country the principle of segregation has now been observed for a period up to 50 years or more—an appendix contains replies to a questionaire on this point from hundreds of sanitary districts—but this has not availed to achieve the effective prevention of the spread of scarlet fever. It is disappointing to learn, writes Sir GEORGE NEWMAN, that the exceptionally high rate of cases admitted to isolation hospitals, which to-day obtains, is not associated with a corresponding lowered incidence rate of the disease in the country as a whole. Nor does length of stay in hospital diminish the chance of the patient reinfecting his home on returning to it. The tendency therefore is for the routine application of these measures to give place to an intelligent application of the new knowledge of the relation of ear and throat conditions to infective processes, to the use of barrier-nursing and open-air treatment, and to the adoption of the Dick test and artificial immunity. If in these ways economy can be effected in the hospital isolation of scarlet fever, the use of beds can be reconsidered in the light of the incidence and severity of infectious disease prevalent in the locality. For in the last decade to set against the 10,672 deaths from scarlet fever there were 58,292 deaths from measles, 392,942 from pneumonia, and 13,645 from epidemic diseases of the central nervous system.

The conclusions reached by the committee of medical officers of the Ministry are based not only on the abundant statistical details obtained from the answers to the questionaire, but on a wide review of all the information available to the headquarters staff. The committee believe that in any well-ordered public health system both hospital isolation and home treatment must play a part; too little

[1] Some Administrative Aspects of Scarlet Fever. Reports on Public Health and Medical Subjects, No. 35. Ministry of Health. London: H.M. Stationery Office. 1927. Pp. 369. 6s.

attention has, they think, been devoted to the possibilities of efficient home treatment. There are districts and towns where home treatment is now being adopted at comparatively little cost and, as far as is known, without harm to the patients or the communities to which they belong. The further provision of nursing facilities would do much to ensure the successful development of these local experiments. In connexion with such home treatment the committee regard it as more rational to practise current rather than terminal disinfection—that is to say, to sterilise as quickly and as thoroughly as possible all articles exposed to contamination by the patient's discharges, and to observe a careful sick-room regimen during the whole time that the room is occupied by the patient. The destruction of remnants of food and fluids which have been handled by the patient demands more attention than it has hitherto received. These and other conclusions are stated in provisional, tentative, and guarded form, for the object of the report is to open the subject to wide discussion, not to close it. If the time is not ripe for universal action, the materials provided by Dr. PARSONS's very able and comprehensive report will bring it nearer.

Annotations.

"Ne quid nimis."

THE TREATMENT OF RABIES.

THIS country is fortunate in its freedom from rabies. Energetic muzzling stamped out the pest completely at the beginning of the century, and again when it was reintroduced in a dog smuggled by aeroplane during the war, and there has now been no case reported for six years. Switzerland and the Scandinavian countries are also fairly free, but everywhere else in the world it remains the same scourge that it was in the Middle Ages. The active immunity given by the Pasteur treatment has mitigated its terrors, but it is still a source of great loss and anxiety, and will remain so until facilities for treatment are so widespread that everyone exposed has immediate access to them. Statistics of the numbers treated are very difficult to correlate and far from being complete, but they show on the whole that the applications for protection grow considerably every year. The dangers of rabies and the existence of its antidote are now fairly well realised in all countries. The authors of a recent Austrian text-book,[1] in dealing with the results of protective inoculation, mention the chief difficulties of estimating the degree of protection it gives—namely, that it is very often unknown whether the bite was really infectious, and that individual immunity is so variable that it is impossible to determine whether any given patient would have developed the disease or not. What does stand out from the figures, however, is the importance of early treatment. With a week's delay the mortality-rate is 0·56 per cent.; with three weeks' delay it is 3·19 per cent. The percentage of fatalities among patients treated on the second day after the bite is only 0·088. The authors conclude that the Pasteur treatment reduces the probability of death in all cases from 10 per cent. to 0·6 per cent.

The method of protection has been little altered since its introduction in 1885, and consists of a series of injections of emulsion of an infected spinal cord which has been dried for varying periods. A dog is infected with rabies and killed at the height of the disease by bleeding; its spinal column is then removed and dried in caustic potash. After 12 or 14 days it loses all its virulence; after eight days an emulsion will still produce rabies now and again on injection into the dura; after five days it will evoke a normal attack, though with a slightly lengthened incubation period, and after four days or less its virulence is unimpaired. The weakening of its effect is purely quantitative. In Pasteur's original schemes the patient was given 14-day emulsion to begin with, the age being reduced by a day at each injection, until on the fifth day of the course he was getting six-day emulsion. Three-day virus was given on about the ninth day (earlier for severe and head-bites), and the whole course lasted 18–21 days. The virus was, of course, of the "fixed" type. After some years of use, however, it was realised that this series was not drastic enough; it let slip too high a proportion of cases, usually those with a more or less massive infection. Once it was realised that the fixed virus was practically non-pathogenic to man, the method was intensified, and the custom of nearly every institute is now to start straight away with five-day emulsion and decrease by a day on each of the first three days. A typical pattern in terms of emulsion-age is 5 4 3 2 4 3 2 3 2 3 2 3 2 2; the dose is 3 or 5 c.cm. daily. Although there has been little coördination between the many Pasteur institutes, the series in use differ but slightly one from another. Högye's method is similar, but dilution is employed instead of drying, and more use is made of variation in the dose. One of the most recent improvements in inoculation technique is that of Philipps. The brain is ground down with glycerine, and can be kept for some months in the dark at a low temperature; when required it is mixed with a 0·5 per cent. phenol and saline solution in the proportion of 1 part to 20. This mixture is heated at blood temperature for 24 hours to sterilise it. Out of 1540 patients Philipps had one death only. The chief technical advantage of this method is that a single substance is used throughout the whole series; the vaccine, moreover, can be transported any distance without losing any of its efficacy.

All these schemes have the drawback of requiring a period of from 13 to 25 days to complete them, and much work has been done to find a way of speeding up the immunising process. This is desirable not only for the convenience of everyone concerned, but for the greater safety of the patient, for the treatment is a race between the antibodies and the invading virus. The authors consider that the quickest and safest method is now that of Hempt, the director of the Pasteur Institute in Novisad, Jugo-Slavia. Brain substance is kept in 50 per cent. glycerine for a period varying from a few days to 24 hours, inversely with the severity of the wound. An emulsion of 1 part in 60 is made up for injection, and the doses fixed likewise according to the nature of the lesion; the total amount given is 4 g. for a head-bite, 3 g. for deep wounds, and 2 g. for slight tears. The treatment takes five days only, and the patient gets two injections a day; the first is of 5 c.cm., the next two of 10 c.cm., then one of 15 c.cm., and the remainder of 20 c.cm. On the last day three injections are given. A very severe case, where there has been a long delay, may have a sixth day of three injections. The results in a series of 2011 patients have been uniformly excellent. One only died, and he had undergone a delay of 16 days. In the latest modification of all, Remlinger proposes to employ undried cord kept in glycerine for varying periods; the virulence of the emulsion will be much greater than that of the preparation of dried substance. The first injection is to be of 25-day emulsion, which is sterile (the virulence disappears suddenly after about 24 days), and succeeding injections will be of rapidly increasing potency. The course is a five-day one. This method has not yet been sufficiently tested to be put into practice. The developments in packing injection-material for transit are perhaps the most important feature of the book from the standpoint of the administrator, for only when every general practitioner in the world can give the protective treatment will the problem of human infection be adequately dealt with. Even then there will remain the infinitely greater one of eradicating the disease from domestic and wild animals.

PASTEURISATION OF MILK IN THE U.S.A.

IT is now more than 30 years since Mr. Nathan Straus, of New York, began his campaign in favour of milk rendered safe by heat. In 1908 he was still fighting for adequate pasteurisation and against commercial pasteurisation by the "flash" process. At that time his definition of adequate pasteurisation was the exposure of the milk to 157° F. for 20 minutes, followed by rapid cooling, whereas by the "flash" process the milk was exposed to varying temperatures above and below 160° F. for perhaps a minute. The U.S. Public Health Reports (Feb. 11th, 1927) show that 28 of the milk-borne outbreaks of infectious diseases recorded during the last 18 years were attributed to inadequately pasteurised milk. The same issue expresses the belief of the U.S. Public Health Service "that pasteurisation of milk is the most potent single force operating to prevent the transmission of milk-borne diseases," and states that the service is at present engaged in a study of apparatus in order to assist milk-control officials to formulate proper definitions and to secure improved methods. The issue of the reports for April 29th carries the matter a stage further. It indicates that flash pasteurisation has disappeared from the scene, and that the majority of State definitions of pasteurisation specify a temperature of 142° F. or 145° F. and a holding time of 30 minutes. The difficulties of securing the desired result are considerable. Even if the thermometer stands at the specified level for 30 minutes it is not certain that every particle of milk will reach the required temperature owing to cold pockets, foam, valve leakage, and unsatisfactory devices for indicating and controlling temperature and time. The inspector may not have all the technical information necessary to make the theoretical definition effective. Should the definition require an "approved apparatus" the local health officer would have to employ a sanitary engineer. And if every particle of the milk has to be pasteurised a higher margin of heat may have to be adopted which will interfere with the cream line, and interference with the cream line will produce serious public opposition to the universal use of pasteurised milk. Illustrations are given in the report of the modified apparatus designed to meet these difficulties. While the tests carried out by the Public Health Service have disclosed many defects these have, we learn, promptly been made good for the most part by modifications made on the spot without the apparatus being returned to the manufacturer.

This report should be of great value to those who have the supervision of pasteurisation in this country. We doubt if the British public is sufficiently interested in safe milk as yet. In reply to a question in Parliament on May 25th it was stated that there are now only 120 pasteurising establishments in England and Wales complying with the Ministry of Health's regulations and their definition that "pasteurised milk" must be retained at a temperature of not less than 145° F. and not more than 150° F. for at least 30 minutes and must then be cooled immediately to a temperature of not more than 55° F. We have heard of milk dealers who have installed a "holder" apparatus, but do not apply for a licence because they find that their customers are not interested in the question of adequately pasteurised milk. Another point arises in view of the American experience. A fee of £1 1*s.* is paid in respect of each plant. Does this imply that the local authority which grants the licence takes any responsibility with regard to the efficiency of the plant? Or, on the other hand, have we adopted the principle that the public health authorities are to judge the efficiency of the plant solely by the periodical bacterial examinations of the milk treated? It is obvious that the regulation that milk must "not be pasteurised more than once" cannot be enforced either by inspection of the plant or by examination of the milk. Furthermore, it does not seem probable that the officials in this country, whose duty it is to inspect the apparatus before the licence is granted, are better equipped with technical information than their colleagues in the U.S.A. All things considered, we cannot expect to get very far with voluntary methods, and ultimately, when further experience has been gained, it may be necessary to enforce pasteurisation of all milk except the two upper grades (Certified and Grade A (T.T.)) if we really wish to secure a safe milk-supply for a public that is not enthusiastic either for or against but rather expects such matters to be arranged for it by the statutory public health authorities.

BLOOD GROUPING IN EUROPE AND AMERICA.

THE nomenclature of blood groups was discussed at a meeting of the Health Committee of the League of Nations, of which a report has just been issued. Dr. T. Madsen, the President, pointed out that there were differences between the nomenclature adopted in Europe and America, and the Committee had been asked to secure international uniformity. The main difficulty was that the problem was not one for governmental regulation, though in a certain number of countries—notably Denmark—it was receiving official attention. There seemed to be no need to hold an international conference, since the question was not so much one of technique as of form. Correspondence would go some way towards defining the difficulties, and eventually a small number of persons might be called together to examine the possibilities of agreement. It was decided that the Section of Hygiene should investigate the problem on these lines.

CARBON TETRACHLORIDE IN THE TREATMENT OF DISTOMIASIS IN SHEEP.

CARBON tetrachloride was first used as an anthelmintic in animals in 1921 by M. C. Hall, then senior zoologist to the U.S. Bureau of Animal Industry,[1] who, in conjunction with Shillinger, in 1923 showed the drug to be an efficient and fairly safe remedy against certain nematodes in the alimentary canal. In 1922 this drug was used by Jeffreys in America against intestinal flukes in foxes, and in 1925 and 1926 was experimentally used in the British Isles for liver fluke (*Fasciola hepatica*) in sheep, by J. H. Norris in Ireland and R. F. Montgomerie in Wales. Since the publication of this experimental work large scale field trials have been made in this and other countries, and reports of the results are being awaited with interest. The drug has been shown to be very efficacious against the adult flukes in the bile-ducts of the liver, but, like extract of male fern, it has no effect upon the immature flukes in the liver parenchyma (the *F. hepatica* reaches the bile-ducts by direct penetration of the fluke embryo through Glisson's capsule). These immature forms become mature and are laying eggs in the bile-ducts in the fourth week after dosage, and consequently further dosage is necessary to destroy them. A dose of 1 c.cm. of carbon tetrachloride in gelatin capsule without previous starvation is sufficient to clear adult flukes from the bile-ducts of the sheep and, speaking generally, sheep will tolerate as much as 30 or 40 c.cm. of the drug in capsule. It is well to note, however, that in occasional instances flocks have been found which tolerate carbon tetrachloride badly and deaths have resulted. This is a matter which is now under investigation in Great Britain. In the meantime it behoves those who are about to use the drug upon sheep to try a few sheep first and find out how the drug is tolerated by the particular flock before dosing large numbers. Carbon tetrachloride possesses advantages in that sheep can be treated without preliminary starvation and can be dosed even when heavy in lamb or with lambs at foot. If further experiments can explain the reasons why carbon tetrachloride should prove toxic in some flocks and not in others, and if this toxicity can be avoided by some simple means, the drug will probably replace extract of male fern as a remedy for the cure of

[1] THE LANCET, 1922, i., 391.

distomiasis in sheep. The presence of impurities has been held by many workers to account for the variations in toxicity. Its application to human parasites was the subject of considerable discussion in 1924.[2] M. Khalil,[3] working in Egypt, has been attempting to discover whether the toxicity is attributable to sulphur impurities. Harold King has found carbon bisulphide in samples submitted to him for testing by the Medical Research Council, but in experimental animals Khalil found that a mixture of carbon tetrachloride and carbon bisulphide had no ill-effects. He is inclined to attribute the toxicity to the presence of sulphur compounds other than CS_2 and gives directions for getting rid of impurities in commercial samples. During 1924 he says that 80,000 people were treated at the Government hospitals by this drug without any fatalities.

PHILOSOPHY.

COMMON experience has amply shown that in education there are two disciplines which have conspicuous merit in helping the mind to learn to think accurately. One is the attempt to find the exact equivalent of the ideas of one nation in the language of another, which is translation. The other is to discover a coherent interpretation of human experience which can be expressed in words, which is philosophy. And anyone knows that medicine is as much in need as any subject of accurate thought and a nice appreciation of the meaning of words. Two years ago the British Institute of Philosophical Studies was founded with the special object of establishing a link between the professional philosophers and the educated public, and its second annual meeting was held on July 4th. The President is the Earl of Balfour, the chairman of council Prof. L. T. Hobhouse, the deputy chairman the Master of Balliol; the council is a long list of distinguished and respected names. There are some 1600 members and more than 500 enrolled for the courses of lectures which were given last winter, among which we notice a series on "Medical Psychology" by Dr. T. W. Mitchell. The Institute also publishes a quarterly journal from 88, Kingsway, London, W.C. 2, and obviously deserves the support of those who are seriously interested in intellectual progress.

THE COST OF NOISE.

THE report on harmful noise, which Prof. H. J. Spooner submitted to the International Fatigue Committee of the American Society of Industrial Engineers on May 26th, should serve to keep attention fixed on this important subject, and contains many observations of general interest. He believes that the most serious aspect of the problem has hitherto not been considered; this is the loss due to impairment of efficiency in industrial life, more particularly by interference with men of affairs and principals, whose capacity for clear thinking and hard work is perceptibly weakened by the babel of noise. He estimates that the economic loss due to this kind of wastage may conceivably be a great deal over a million pounds a week in this country alone; and though this figure may well be an over-estimate, no one will deny that the attempt to do mental work in noisy and distracting surroundings tends to lower efficiency and produce irritability. The uproar of mechanically-propelled traffic and of other machinery in our streets is the most serious source of noise, and the noisy environment of hospitals, nursing homes, and schools calls for earnest attention. Prof. Spooner believes that the most nerve-shattering sound in our streets is caused by tramway-cars; he considers that these vehicles have lost most of the reasons for their existence since the introduction of motor omnibuses, and points out that they are being gradually scrapped and are doomed to ultimate extinction. Here, perhaps, the thought is but the offspring of the wish, in which many motorists must share from ulterior motives. He makes other recommendations of interest to motorists—namely, that noisy ramshackle motor vehicles should be warned off the streets, that motor horns should be standardised to a low melodious pitch, that louder hooters should only be used in emergencies, and that "driving-on-the-hoot" should be prohibited. Such reforms are undoubtedly desirable, though difficult to enforce, and a beginning ought to be made in the attempt to diminish the uproar of the streets. The further proposal is made that the pneumatic rock-drills, used for breaking up roads, should not be permitted in towns, and certainly not in the vicinity of hospitals and schools. In factories and works, Prof. Spooner urges, designers of machinery should pay more attention to the balancing of rotating parts, particularly of those working at high speed, and to the mounting of certain machinery on antivibration supports; noisy machinery means excessive wear and waste of power, and the noise tends to reduce the productive powers of the workers and may be a cause of accidents. We hope that the movement for the reduction or prevention of harmful noise will achieve its object by awakening public opinion.

THE PREVENTION OF DENGUE.

THOUGH not in itself serious, dengue is a very uncomfortable disease, and causes a considerable loss of service. During 1925 818 cases were reported from the army in India; no statement is made as to the average time lost, but in naval cases during the previous year it was eight days. The incidence of the disease at Aden is discussed by Major G. H. Dive in the *Journal* of the Royal Army Medical Corps for April. After examining the clinical records of the station for the last few years, he concludes that there is a short term fever endemic there, appearing every summer, and always dengue though often otherwise named. The troops become infected from April to July, afterwards acquiring a considerable degree of immunity, perhaps lasting two years, so that the infection only becomes prevalent again if a new regiment has reached Aden later than July. Major Dive ascribes dengue to the abundantly present mosquito *Aëdes argenteus*. Though the local fever is sometimes called sand-fly fever, he has never seen a case of that disease at Aden, nor has he seen a phlebotomus there.

An epidemic of dengue occurred at Saigon in 1926, very fully and instructively reported by Dr. R. Pirot, a surgeon in the French Navy,[1] special attention being given to the cases on his own ship, *Craonne* (125 men). She reached Saigon from France in February, and on April 25th one of the crew returned from leave at Cape St. James and slept on the upper deck, unprotected by a mosquito net. On April 28th he sickened with what was later found to be dengue. As Dr. Pirot suggests, the subsequent history is illuminated by the work of Siler, Hall, and Hitchens.[2] Female *Aëdes egypti* (*stegomyia fasciata*) no doubt bit the first patient; after 11 days they became infective and bit other men of the ship who developed dengue from four to six days later. Sixteen cases came under notice between May 15th and 31st. In June dengue spread to other ships and establishments and Dr. Pirot saw 130 cases in the hospital; 80 per cent. of the Europeans of *Craonne* were attacked. There were on board her many *Aëdes egypti*, particularly gorged females, more of them being on the side of the mess-deck next the quay than on the outer side next the stream. Like Major Dive, Dr. Pirot notes the difficulty in such a climate of making men sleep under mosquito nets, and his opinion is that the aëdes mosquitoes should be exterminated, so that there would be no more dengue. Valuable information about the means of extermination of *Aëdes egypti* will be found in a paper[3] by Colonel W. P. Chamberlain, Medical Corps, U.S. Army, the chief health officer of the Panama Canal. Discussing

[3] Military Surgeon, April, 1927.

the prevention of yellow fever for 22 years, extinct in the Canal Zone (unless imported), he points out that *Aëdes egypti* is a short-flying, domestic species which develops almost exclusively in artificial water-containers in the house or yard, and that its reproduction is best prevented by a properly piped water-supply, making cisterns unnecessary and permitting tanks and wells to be closed. The rest is conservancy, and breeding must cease if inspection does away with broken pots, old tins, sagging gutters, and the like which make casual pools in the rains. Besides, aëdes remain located in the house where they are infected and can be killed there by fumigation or otherwise The lesson appears to be that dengue need no longer be endured, since aëdes can be got rid of so much more cheaply than anopheles. Meanwhile, seeing that patients with dengue, as with yellow fever, are only infective to aëdes in the first three or four days of their illness, we must learn to diagnose the condition at once and put the patients under mosquito nets, while the mosquitoes that have been near the patient in his house or ship should be all immediately killed.

The essential, however, is to make it impossible for these mosquitoes to breed. That is how Gorgas banished yellow fever from Havana and the Canal Zone, and surely we might do as much at Aden and elsewhere now that the stages on the road have been made so plain.

THE EVOLUTION OF VACCINIA VIRUS FROM EPITHELIOMA CONTAGIOSUM.

IN a recent article on the mechanism of virus infections [1] we drew attention to a remarkable phenomenon exhibited by many virus diseases, which has no counterpart in bacterial diseases. Many virus infections in their clinical behaviour and in their spontaneous infectivity appear to be distinct and specific diseases. But experimental transmission can often break through this specificity and thus establish the same causal agent for apparently distinct virus diseases. Evidence is gradually accumulating that the vaccinia virus, for instance, can affect widely different species and there set up lesions which formerly were considered to be distinct diseases. Thus the observations of Heelsbergen and of Toyoda on fowl-pox, and of Zwick on stomatitis pustulosa contagiosa of the horse, have shown that these diseases are closely allied to each other and to Jenner's horse-pox and other animal variolas. A recent paper by Dr. C. G. Pandit [2] adds further evidence on this point. By intracutaneous inoculation of calves with the infective material from epithelioma contagiosum of fowls and subsequent repeated passages through calves, monkeys, and back to calves again Dr. Pandit claims to have evolved a strain of vaccinia virus producing the typical lesion and conferring immunity to inoculation with vaccinia virus. An interesting point is that calf passages alone are not sufficient to effect this development, but that the interposition of a passage through monkeys is necessary. The skin and cornea of rabbits reacted negatively to inoculation with the infective material taken directly from fowl-pox. But when inoculated with passage material obtained from different stages of development of the strain, a successful reaction was obtained first on the cornea, and in later stages of development also on the skin. In our article, referred to above, we pointed out in connexion with recent work on mosaic disease of plants that many of the apparently paradoxical phenomena observed in the experimental transmission of virus diseases may be due to the fact that the infective material is loosely identified with the "virus." But actually in transmitting the disease the whole infected tissue is used and this in addition to the virus probably contains other substances which modify and determine the pathogenic action of the virus. The present series of observations present features very similar to those recorded in the transmission of mosaic disease from one species of plant to another and are capable of the same explanation.

TYPE CULTURE COLLECTIONS.

THE recent publication [1] of the catalogue of the cultures maintained by the American Type Culture Collection is a reminder of the solid if unobtrusive progress that has been made in recent years in the equipment and maintenance of new collections of bacteria and of the remodelling of existing ones. In the years before the late war the principal source of world supply was provided by the collection maintained by Král on a commercial basis at Prague. This collection was, after the war, transferred to the Serophysical Institute at Vienna, where it is under the direction of Dr. Ernst Pribram. In addition, the collection of the Pasteur Institute in Paris maintained by Mr. Binot and the private collection of the Lister Institute in London formed other sources of supply. But these were not widely available and were for the most part confined to bacteria of purely medical interest.

In 1911 a Bacterial Collection and Bureau for the Distribution of Bacterial Cultures was established at the American Museum of Natural History in New York City under the curatorship of Dr. C. E. A. Winslow. In 1922 the collection was transferred to the Army Medical Museum in Washington, D.C., and was placed under the control of the Society of American Bacteriologists, pending more permanent arrangements. For the last couple of years the collection has been under new management and has been housed in Chicago at the John McCormick Institute for Infectious Diseases, with Dr. G. H. Weaver as curator and under the general direction of a committee representing the Society of American Bacteriologists, the American Phyto-pathological Society, the American Zoological Society, and others. In addition to the organisms actually maintained at the Institute, the private collections of special workers, such as the mycological collections maintained by Dr. Charles Thom and Miss Margaret B. Church at Washington, D.C., and the soil actinomyces maintained by Dr. S. A. Waksman at New Jersey Agricultural Experiment Station, are available to the American research worker through the good offices of the Type Collection. The catalogue which has been issued recently to some extent follows the form that has been adopted by the National Collection of Type Cultures in this country, and is of interest to general and special bacteriologists and to the systematist. The whole-hearted adoption of the classification devised by Bergey in his "Manual of Determinative Bacteriology" is not, however, beyond criticism, especially as the system of nomenclature has not met with anything like universal acceptance even in the United States. This criticism is in no way directed against the general labours of American systematists, who have accomplished much valuable spade work in this field and whose researches in general systematic bacteriology will be of the greatest assistance when the whole question of bacteriological nomenclature comes up for consideration—as we understand it may—at the next International Botanical Congress to be held in 1930.

In our own country the long-considered scheme of the Medical Research Council (then the Medical Research Committee) for the formation of a National Collection of Type Cultures bore fruit in the years following the war. In 1920 the Council were able, by courtesy of the governing body of the Lister Institute of Preventive Medicine, to make such a collection at the Institute under the general direction of Prof. J. C. G. Ledingham and the curatorship of Dr. R. St. John-Brooks, the existing collection of the Lister Institute forming a nucleus for future develop-

[1] American Type Culture Collection. Catalogue of Cultures, 1927. Waverly Press, Inc., Baltimore.

ment. Over 2000 strains of micro-organisms are now maintained there, and some thousands of cultures are distributed every year to workers in this country and abroad. In addition to supplying bacteria of importance in human and veterinary bacteriology the bureau has a collection of representative fungi of pathological and economic importance, and a collection of yeasts and other organisms of use in fermentation and allied industries. In this way many important strains have been preserved which otherwise might have been lost owing to changes in the personnel in charge of private collections elsewhere. For example, the Karlsberg Collection of yeasts and allied organisms is no longer kept on its previous basis, and many valuable strains might have been permanently lost if facilities had not been available for maintenance elsewhere. The mycological section of the National Collection is under the supervision of a standing committee of the British Mycological Society, which includes representatives of most of the important botanical institutions and teaching bodies in this country and has already been of considerable service to mycologists at home and abroad. In this connexion mention may be made of the Centralbureau voor Schimmelcultures, at Baarn, Holland, which is also available to British workers. Over a thousand species of fungi are kept there, and the collection is being constantly augmented. In addition to these establishments, private collections, many of them supplied in part from the resources of the British collection, are maintained in increasing numbers in various countries. Some of these, at any rate, may be considered as nuclei for future national culture collections. There is room for all, and they will all serve a useful purpose, giving ready and willing service to the workers in the local field and forming centres of exchange and friendly relationship with the collections of other countries. In this way valuable and historic strains will insure their maintenance, and increased facilities for comparison and for typing purposes will be available to workers throughout the world.

THE REPRESENTATIVE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE representatives of the British Medical Association when they meet at Edinburgh this week-end will have their first opportunity of considering as a body the recommendations of the Royal Commission on Lunacy, for the report of the Commission appeared just after the conclusion of the Nottingham meeting last July. To assist the meeting in its discussion of the report the Lunacy Committee of the Association has drawn up a critical memorandum from which it appears that in two matters of prime importance the policy of the Association is at variance with that of the Commission. These concern the protection for medical practitioners who sign certificates under the Lunacy Acts, and the facilities for treating the earliest manifestations of mental disorder. Suggestion is made that the Representative Body of the Association should press for introducing into the judicial detention order words indicating that before signing the order the judicial authority has satisfied himself that the medical practitioner concerned had exercised reasonable care. Such a statement would establish a presumption in favour of the practitioner should his conduct be brought in question subsequently. As to the facilities for treating early mental disorder, a recommendation is made by the Council of the British Medical Association that specialist work in connexion with the treatment of patients suffering from mental disease in its early stages should not be carried out by whole-time medical officers of public health or local government authorities, but on a part-time basis by medical practitioners who have special knowledge of the subject. The Royal Medico-Psychological Association, on the other hand, suggests that to divorce the diagnosis and treatment of mental disease in its early and late stages is scientifically and administratively unsound, and that the implied contention that medical staffs of public mental hospitals are not competent to treat early cases of mental disorders is ill-founded. Other subjects likely to provoke discussion at the representative meeting are the proper functions of laboratories under public health authorities; the allocation of any fees received for pathological work done in hospitals or medical schools from patients able to pay; and the attitude of the profession to the establishment by trading firms of laboratories as subsidiary enterprises for the purpose of offering pathological examinations and reports on individual cases.

THE ROYAL SANITARY INSTITUTE.

THE Thirty-eighth Congress of the Royal Sanitary Institute began at Hastings on Monday, July 11th. The members, numbering about 1500, included over 800 delegates appointed by local governing authorities in this country and also representatives of foreign Governments, India, the overseas dominions, universities, learned societies, and voluntary associations interested in health work. The Mayor of Hastings received the delegates and a public luncheon followed. In the afternoon the health exhibition was declared open, and later the Home Secretary, Sir W. Joynson-Hicks, delivered his presidential address. He referred to the organisation of the police forces and of the public health services as two of the great political achievements of the nineteenth century. Much had been done in the last 50 years, but much remained to be done. Many slums still existed. We had cleaned our streets, but we had still to clean our skies. He referred especially to the administration of the Factory Acts, which covered places in which 6,000,000 persons were employed. Large numbers of the workers could not return home to dinner, and remained in the atmosphere of the factory for three-quarters of their waking day. A new factory Bill was to be put before Parliament next session. It was 26 years since the last general factory Act was passed, and the object of the new Bill was to bring the backward factories up to the level reached by progressive employers. The standard of cleanliness was not always high, perhaps because women had taken no hand in it. The new Bill would strengthen the provisions as to cleanliness with the object of improving the health and efficiency of the workers and in food factories with a view also to the protection of the public. The tonic effect of better lighting would also have attention, and better ventilation would be aimed at, particularly to cope with the lowering of bodily vigour by stagnant air. Personal hygiene was another important matter to be fostered by the provision of cloak-rooms, washing facilities, overalls, and so forth. In a food-packing factory a higher standard of hand cleanliness had recently been secured by the provision of manicure treatment. Medical examination was recognised as a useful preliminary to work in factories, and re-examination in certain dangerous trades was required in order to prevent industrial disease in its early stages. About 15,000 cases of sepsis occurred in the factories in a year, most of which could be prevented if the workers made use of the first-aid boxes provided. Many employers now provided dental clinics. Further provision would be made in the new Bill for medical supervision, especially in industries where there is a low standard of health or a high sickness-rate. It was not proposed, however, to make the appointment of a factory doctor compulsory; no evidence had been submitted to justify such a step, and it was not clear that there was a demand for it by the workers of the country. In conclusion, the President referred to the many-sidedness of public health, to its positive as well as its negative tasks, and quoted the definition of hygiene as an art of which the practical aim is "to render growth more perfect, decay less rapid, life more vigorous, death more remote." The work of the congress, which is distributed over six sections, and seven conferences, began in earnest on the following day with the opening of the Section of Sanitary Science and three of the conferences.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXII.

THE TREATMENT OF CORNEAL ULCERATION.

ULCERATION of the cornea is probably, in the majority of cases, the result of trauma. But, in most cases, the trauma is of very slight degree, and the resulting ulceration is due to the fact that the condition of the cornea, conjunctival sac, and general state of the individual are favourable to the advance of septic processes. There is, however, a comparatively large minority of cases of ulceration of the cornea where the ætiology is different. In these cases bullæ form around the nerve-endings in the corneal epithelium, and these bullæ soon break down, forming small ulcers, usually multiple and often grouped in a branching pattern in the central zones of the cornea. This is the type of corneal ulceration often seen in association with febrile states, and is a peripheral expression of a poisoning or irritation of the nerve or nerve ganglion, and is not primarily the result of trauma. Mention should also be made of the ulceration of cornea associated with phlyctenular disease. The treatment of all types of ulceration is, generally speaking, the same.

Corneal ulceration, except in certain indolent cases in elderly people, causes extreme discomfort and pain —in bad cases very severe pain. Photophobia is characteristic of all corneal lesions, and often a marked blepharospasm, leading to a spasmodic entropion of the lower lid, is present. The pain is located to the site of the lesion, but in the more severe cases, in which there is an associated iritic engorgement, there will be in addition much circumorbital and temporal pain, often neuralgic in character. In the early stages the eye, on examination, will be found injected. The injection will be most marked in the region of the limbus, immediately around the cornea, and it will be both superficial and deep—the superficial conjunctival vessels being engorged, and the deeper vessels in the sclera also, these latter giving a deeper homogeneous bluish-red coloration to this region. If the corneal lesion be small, it may be hard to see; it may be rendered more easily visible by instilling into the conjunctival sac a drop of 1 per cent. fluorescein, followed by a few drops of saline, after which the ulcerated area will be stained a greenish-yellow colour. An early corneal ulcer will appear as a small, usually roundish, grey area, its margins fading off gradually into the surrounding clear cornea. Later, or in more severe cases, an increasingly large area of the cornea will be involved, and, in extreme cases, the whole cornea may be affected. The ulceration may take a crescentic shape, the convexity of the ulcer pointing mesially, extending in this direction and burrowing deeper as it grows into the corneal tissue. In some cases cellular exudation makes its appearance in the anterior chamber and is seen as a yellowish layer lying at the bottom of the anterior chamber, having a flat upper border. This layer, known as hypopyon, indicates that the condition is a severe one. In elderly people a rather indolent form of ulceration is sometimes seen; here the situation of the ulceration is marginal, just inside the corneo-scleral junction, and the ulcerative area may be fairly extensive in a radial direction, but does not usually extend centrally.

General Measures.

Certain general considerations should be kept in mind. The fact that a septic process has established itself and is in progress suggests that the patient's resisting powers to infection may be reduced. It is necessary, therefore, not to neglect his state of health, the condition of his bowels, the presence of other foci of sepsis, and so forth.

Local Measures.

The Lacrymal Sac.—As to the eye itself, it is of paramount importance to investigate the lacrymal excretory apparatus. Pressure should be made over the lacrymal sac and the two punctal openings watched carefully for the presence of regurgitation; it may even be well to syringe fluid through into the nose in order to ensure that these passages are patent. If regurgitation from the lacrymal sac is found it is necessary to deal with this at once, as here will be almost certainly the cause of the corneal infection. The best procedure is to excise the sac forthwith. If for some reason this cannot be done, it is possible to seal up the two canaliculi by passing the cautery into them or by tying a suture around them, but this is by no means so satisfactory as the excision of the sac.

Ointments.—Having made sure of the condition of the lacrymal sac, the next thing is to treat the eye itself. The routine basic treatment of a corneal ulcer is the instillation of atropine ointment into the conjunctival sac, and the application of a firm pad and bandage. 1 per cent. atropine ointment should be used, and it is quite a useful practice to incorporate 1 per cent. yellow mercuric oxide ointment with the atropine ointment, the yellow mercuric oxide ointment having a stimulating and antiseptic effect. The ointment should be applied to the eye two or three times in the 24 hours, and just before the ointment is put in the eye should be bathed with warm boric lotion. The best way to do this is with an undine, or if this is not obtainable, to drip the lotion into the conjunctival sac with a sponge. All the intervening time a firm pad and bandage should be kept applied; an eye-shade is useless and its use in these cases is to be deprecated. The bathing of the eye should not be overdone, and in fact excessive irrigation is harmful. In slight cases of corneal ulceration it is perhaps not necessary to confine the patient to bed, but it is well to do so if the case is a severe one or shows signs of progressing.

Heat.—The firm pad and bandage generally tends to relieve the pain to a great extent, but where the pain persists, and especially where the circumorbital pain indicating an associated iritis is present, the use of dry heat over the pad by a hot box or electric apparatus, and the application of leeches to the temple of the affected eye will afford much relief. The usual analgesic drugs, such as aspirin, are in no way contra-indicated.

If the conjunctival sac appears in a septic condition, it may be well to use protargol drops, 5 per cent., twice a day, in addition to the above procedure. In some cases magnesium sulphate, 5 per cent., used as drops, or as a lotion twice a day, appears to give very good results, particularly in the bad ulcer cases associated with a hypopyon.

Intractable Cases.

The majority of corneal ulcer cases will respond to treatment carried out on the above lines. If, however, the ulcer appears to be progressing, it will be well to attack the ulcer itself. This is most easily done by applying pure carbolic acid to the ulcer. The procedure is as follows.

Carbolisation.—A drop of 4 per cent. cocaine is instilled into the eye and the lids are held apart, preferably by a lid speculum. The surface of the ulcer is dried by laying a clean piece of blotting-paper upon it. A small pointed piece of wood—a sharpened match will serve the purpose very well—is dipped into the pure carbolic and is then applied to the ulcer. (The match should be well soaked, but no drop should hang from it.) It is well gently to curette the ulcer before applying the carbolic; usually there is a small amount of débris lying in the centre of the ulcer, and this should be removed first. Carbolisation of a corneal ulcer has the advantage that it is comparatively easy to do and can be repeated at frequent intervals. In bad cases the actual cautery at dull red heat may be applied to the ulcer with advantage.

Paracentesis of the Anterior Chamber.—If the ulcer extends in spite of the cauterisation, and especially if there is a large hypopyon present, as is usual in such cases, the question will arise as to whether paracentesis of the anterior chamber should be performed. This

procedure anticipates the actual perforation of the ulcer itself, and by relieving the tension on the corneal tissue favours resolution. If, in spite of all these measures the ulceration still progresses, all hope of saving good vision in the eye will have gone, and it will become a question of attempting to keep the eye in the head with some sort of vision. In such a state of affairs section of the cornea (Guthrie's or Saemisch's section) should be performed. A fine cataract knife is entered at one side of the cornea and pushed through the anterior chamber and out at the other side of the cornea, and then made to cut out vertically through the whole breadth of the cornea. In a remarkably high percentage of such cases, after this has been done the progress is stayed and the eye slowly quietens down. Should this not happen it will probably be necessary to eviscerate the globe.

Prognosis as to Vision.

If the process of ulceration has only involved the corneal epithelium complete resolution with absolute transparency will result; in the majority of cases of septic ulcer, however, the process will have involved the substantia propra of the cornea. The corneal tissue proper does not regenerate completely and an opaque scar will be the result. It is possible, after the actual ulceration has healed, to modify the opacity of the resulting scar to some extent by the use of such measures as insufflations of powdered calomel, the instillation of dilute yellow oxide of mercury ointment, or dionin drops 5 per cent. Too much, however, must not be expected from these measures. If the corneal scar occupies the centre of the cornea and obstructs the pupil, it may be possible to improve vision by performing an optical iridectomy, which will enlarge the pupil so as to extend under a clear, or relatively clear, portion of the cornea. Tattooing of the corneal scar with Indian ink will improve the appearance considerably and, in slight scars, will actually improve vision by making them more opaque and so preventing them from refracting light irregularly.

BRIGHT'S DISEASE.

THE CENTENARY OF THE DISCOVERY.

ON the occasion of the centenary of the discovery of Bright's disease by the great Richard Bright, who was physician to Guy's Hospital from 1820 to 1843, an interesting ceremony of celebration was prepared by the hospital.

The proceedings commenced on Friday, July 8th, at 11 o'clock, when Prof. Ludwig Aschoff, of the University of Freiburg, gave a demonstration of the pathology of Bright's disease; Dr. John Fawcett took the chair in the Anatomy Lecture Theatre.

Disorders of the Kidneys with Symptoms of Bright's Disease.

Prof. Aschoff, disclaiming any intention of discussing all the symptoms in the complex clinical picture denoted by the term Bright's disease, made a classification based upon the cardiac conditions, following here Bright's own example. In distinguishing the cases without hypertrophy from those with it, Prof. Aschoff assumed that acute initial changes in the kidney were not in question, and concluded that the clinical phenomena, which should occupy the central interest, were glomerulo-tubular nephritis and arterio-sclerotic or genuine contracted kidney. In a brief recapitulation of the whole subject he evolved the following scheme:—

(*a*) *The so-called Nephroses.*—Without increase of blood pressure or hypertrophy of the heart. Marked albuminuria and œdema. Abnormal permeability of the cutaneous and renal vessels for albumins and lipoids (lipoid dystrophy of the kidneys), referable to changes of metabolism.

(*b*) *Glomerulo-tubular Nephritis.*—(1) Acute stage. *Acute glomerulitis* and *glomerulo-nephritis.* Acute dilatation of left heart with acute hypertonicity. Acute œdema. Marked albuminuria. Infectious-toxic lesions of cutaneous and glomerular vessels. (2) Subacute stage. *Large mottled and white kidney.* Intermittent œdema. Variable albuminuria. Slight or absent hypertrophy of the heart. (3) Chronic stage. *Secondary contracted kidney.* So-called smooth contracted kidney. Variable albuminuria, especially during a relapse. Repeated, so-called renal œdema. Death most frequently in uræmia.

(*c*) *Arterio-sclerotic Contracted Kidney.*—Begins with hypertonicity. Secondary morphological changes of arterioles of abdominal glands, especially kidneys. (1) Precirrhotic stage. So-called *idiopathic hypertrophy.* Death from apoplexy. (2) Cirrhotic stage. So-called *granular atrophy of kidneys.* Marked hypertrophy of heart. Slight albuminuria. Œdema static. Death from heart failure or cerebral apoplexy as result of athero-sclerosis of small cerebral arterioles.

(*d*) Special or combined renal diseases. (1) *Focal embolic glomerulo-nephritis of* Loehlein with thrombo-endocarditis ulcerosa lenta. Doubtful transition to secondary contracted kidney. Hæmaturia, less albuminuria. Mixed œdema, presumably chiefly cardiac. (2) Arterio-sclerotic contracted kidney with recent arteritis and glomerulitis. So-called *malignant sclerosis* of Fahr. Death from uræmia. (3) Secondary contracted kidney with subsequent sclerosis of arterioles. Death from heart failure, apoplexy, or uræmia.

If we compare this scheme with Bright's introductory remarks to his Selected Reports of Medical Cases of the year 1827 we see that Bright insisted on the separation of all the forms of œdema which can be explained by local heart failure or circulatory disturbances, or by disease of the lungs or liver, from true dropsy, as it is found in lesions of the kidneys. Only the *nephroses* and the *glomerulo-nephritides, together with the resulting secondary contractions of the kidneys,* are to be designated by the term disorders of the kidneys with symptoms of Bright's disease in its strict sense. The arterio-sclerotic contracted kidneys, with their prevalent cardiac œdema, do not belong here. But since Bright himself figures kidneys of this kind and does not always distinguish sharply between the different sorts of œdema, but only considers the coexisting kidney trouble to be essential for his classification, we must include arterio-sclerotic kidneys in our consideration of renal disorders with symptoms of Bright's disease. But we must realise fully that the expression "symptoms of Bright's disease" is more suitable than "Bright's disease of the kidneys," since the latter embraces too many things. Even the term "symptoms of Bright's disease" is quite vague enough, and requires further qualification. It might be well to use this centenary to give a narrower definition to "the symptoms of Bright's disease" and to *limit them to those symptoms that are presented by toxic and inflammatory albuminuria and the so-called renal hydrops.* These symptoms of Bright's disease in the narrower sense are found only with the so-called nephroses (lipoid-dystrophies), the glomerulo-nephritides, and the glomerulo-nephritic contracted kidneys. Since the nephroses are relatively rare, and still form a much-disputed chapter, it follows that *the symptoms of Bright's disease are, and will be, associated for us with the idea of glomerulo-nephritis and the glomerulo-nephritic contracted kidney.*

A Physiological Discourse.

At noon Prof. Lemierre, of the University of Paris, who had taken Prof. Widal's place at very short notice, delivered a discourse on selected cases of Bright's disease in the Physiological Lecture Theatre, when Sir William Hale-White took the chair.

The Bright Oration.[1]

At 1.30 a party of distinguished guests were entertained to luncheon in the Governors' Court Room, among those present being the Earl of Balfour, who presided later in the Physiology Theatre at the delivery of the Bright Memorial Oration by Dr. W. S. Thayer, Emeritus Professor of Medicine of the Johns Hopkins University, Baltimore.

Prof. Thayer first outlined in detail Bright's general education at Exeter and in Edinburgh, including a brief account of his well-known expedition to Iceland with Sir George Steuart Mackenzie. In dealing

[1] This report is an abstract of the full Oration which will appear in the next volume of the Guy's Hospital Reports.

with the early work at Guy's Hospital he made the interesting note that it was through the stimulus of Astley Cooper that Bright early gained his interest in morbid anatomy, while another of his teachers William Babington, interested him in geology. He returned to complete his medical education in Edinburgh and then, after keeping two terms at Peterhouse, Cambridge, went for various periods during 1814, 1815, 1816, and again in 1818 on to the continent, travelling often through scenes of war. He recorded his various experiences in a volume published in the last-named year illustrated with sketches made with his own hand.

This book, said Prof. Thayer, gives one the picture of a young man of six-and-twenty who is capable of observing and describing the customs and life of a people new to him with measure and charity and understanding, seeking out and recognising that which is good, and never allowing a hasty or an unkind criticism to escape his pen; such measure and such understanding were not, said the orator, common at six-and-twenty, but were characteristic of Bright throughout. In 1820 he became assistant physician at Guy's Hospital, and in the same year his scientific accomplishments, proved by his studies in geology and botany, were acknowledged by election to the Fellowship of the Royal Society.

Of Bright's work in the hospital the orator said:

"From the day he entered Guy's Hospital he devoted himself whole-heartedly to the study of morbid phenomena, year after year spending as much as six hours a day at the bedside and in the necropsy room. Occasional notes of cases demonstrated during his visits show how carefully, even at this early period, he observed and noted the recondite; an example is a good description of what, obviously, was an instance of syringomyelia. For seven years he published little or nothing, but never were seven years better spent. On the 13th of August, 1826, Laënnec died, leaving the legacy of his great work with the immortal descriptions of tuberculosis, of pneumonia, of bronchiectasis, of emphysema, the work which laid the foundations of modern physical diagnosis of diseases of the chest. Bright took up the torch and, a twelvemonth later, one hundred years ago, but three years after he had come into his wards, rendered a noble account of his stewardship at Guy's Hospital in the shape of a beautiful quarto volume entitled Reports of Medical Cases Selected with a View of Illustrating the Symptoms and Cure of Disease by a Reference to Morbid Anatomy. This remarkable publication was a careful, laborious collection of observations, clinical and anatomical, made for the most part during the three years of his service as full physician, together with such conclusions as he felt justified in drawing—'an attempt,' says he 'to render the labours of a large hospital more permanently useful by bringing together such facts as seemed to throw light upon each other . . . . To connect accurate and faithful observation after death with symptoms displayed during life must be in some degree to forward the opportunities of our noble art.' He is not trying to lay before his readers a succession of striking novelties; utility is his first object. His work will not 'in theory at least be thoroughly completed until every disease which influences the natural structure, or originates in its derangements, has been connected with the corresponding organic lesion.'"

Prof. Thayer then briefly described what was the accepted knowledge when Bright began his extensive studies.

He mentioned, as characteristic of Bright's thoroughness that, when describing some illustrative cases he made an allusion to the altered structure in a kidney, observed in the post-mortem examination of a patient 12 years previously, and produced the sketch which he had made at the time. A second quarto volume of Reports of Selected Cases soon followed, and some three or four years after the earliest observations were made we find that his work had become the object of world-wide interest and discussion. In 1836, in the first volume of Guy's Hospital Reports, he gives a more or less complete summary of his work, and Prof. Thayer enumerated the headings of many of the remarkable records, noting that Bright had actually recounted many instances of Jacksonian epilepsy, had recognised the significance of the syndrome, and had described it repeatedly and with great clearness. Bright also described with singular accuracy two instances of amnestic aphasia with central lesions. The second quarto appeared but seven years after Bright had acquired the opportunities offered by wards of his own. The quiet, modest young man, who had schooled himself from the beginning to observe, to note, to picture, to record all that which he could grasp of nature and her works, had been true to his promise; in his medical inquiries he had shown the same keen, sure power of observation, the same industry, the same mental poise, the same sound, sane judgment that he had manifested in his earlier writings. At the age of two-and-forty he had seen and comprehended and recorded and illustrated his experiences in communications which stand out among the great contributions to medicine. In 1832, following the publication of his second quarto, Bright was promoted from Licentiate to the full Fellowship in the Royal College of Physicians.

Prof. Thayer next reviewed the contents of the first volume of the Elements of the Practice of Medicine, written by Richard Bright in association with Thomas Addison. The second volume was never published and Dr. Thayer alluded in appropriate terms of comic contempt to the uninformed nature of the reviews which the book received. Bright, he said, examined that which was before him with an objectivity which amounted almost to genius. That which he observed he *saw*, he remembered, he appreciated; often he recorded. To him who knows how to observe, who has that which we call "insight," to him Truth reveals much that she hides from the many. A disinterested lover of truth, he was oblivious of questions of priority or of personal fame, going out of his way to give credit to his colleagues and to his associates for work done at his suggestion and under his direction. He lost nothing by his generosity. For generosity fame has a sharp and comprehending eye.

An amusing interlude in the oration was furnished here by a description of the activities of one Richard Bright, M.R.C.S., the author of a popular treatise on the "Diseases of Females: Every Woman's Book or Female's Physician." It is hard to believe that this work, which obviously was not scientific and was written mainly in the interests of its author, should have been actually ascribed for nearly 50 years, in one important medical bibliography at least, to the great Richard Bright whose work is not alluded to in the book. Richard Bright paid no attention to the ungenerous comments made upon himself owing to the confusion of personalities, and he treated with equal contempt certain quack advertisements which appeared to allude to his successes in an unprofessional way, "though THE LANCET made fervid protests."

Of Bright's prescience in forestalling at Guy's Hospital what is now the accepted method of conducting medical research—namely, by coöperation and team work—the orator said:—

"Bright had enjoyed the privilege of his position at Guy's for nearly 20 years. He had made the most of his opportunities and had observed keenly and recorded accurately and conscientiously that which he had observed. That 'chastened power' of generalisation and the 'cautious habit of reasoning upon facts' which he had urged upon his students had enabled him greatly to enrich medical literature. He had become an international figure and one of the leading consultants in London. In 1843, at the early age of four-and-fifty, he resigned the hospital positions of which he had made such good use. But the last use that he made of his service was notable. In the spring of 1842 he obtained the permission of the authorities of Guy's to set aside two clinical wards, 42 beds in all, for a period of six months, for the intensive study of renal disease; in his own words 'to examine, as far as it was possible, the changes which accompanied the secretion of albuminous urine in the various functions and secretions of the body; whilst at the same time we registered the various circumstances connected with the origin, progress, and treatment of the disease;—a disease than which there is certainly none which offers a more extended field for well-directed observation.' This experiment, which Bright regards as the first yet made in England 'to turn the ample resources of an hospital to the investigation of a particular disease, by bringing the patients labouring under it into one ward, properly arranged for observation,' was wisely conceived and well executed. Between the two wards was a consulting and registration room with a communicating laboratory—what we should call a 'clinical unit.' The results were published in the Hospital Reports for 1843 in the names of his chief associates, Barlow and Rees, with a short prefatory note by Bright. The communication is a fitting climax to Bright's labours on renal disease, and marks in striking manner the progress which clinical medicine had made in his day; detailed clinical histories; thorough and accurately recorded physical examinations; careful necropsies; chemical studies of the blood and fluids by Rees, who sets forth the hydræmia; the existence in the blood of one of the ingredients of the urine its like presence in milk and fluids effused in various cavities the deficiency in the urine of one or more of its natural ingredients, the hyposthenuria, the albuminuria.

"But what is yet more striking and quite characteristic is that these studies, planned, inspired and directed by Bright, should have been published in the name of his associates who had done the detailed work—that his name should have appeared only in the preface, while h

scrupulously mentions the names of Barlow's internes and Rees' laboratory assistant."

With the following eloquent words the oration closed :—

"One cannot look back on this life of unusual achievement without a sense of warm admiration for the man. Happy in his birth and in the surroundings and conditions of his early life, cultivated by travel and society, an artist, a linguist, a man of scholarly tastes, Bright made full use of his opportunities. Modest, simple, high-minded, mellowed by the broadening and softening influences of the experience of a practising physician, Bright appears to have been in the true sense of the word a gentleman, possessed of the μεγαλοψυχία of Aristotle, one who moved among men, high and low, with courtesy and sympathy and charity. His equanimity, the sober restraint of his language, his studied avoidance of intemperate or provocative words or acts, excite one's admiration. He seems to have had a rather unusually winning simplicity and purity of character, to which his obituary notices bore touching testimony. He was a great observer. He was not given to hasty speculation. His mind seemed never to wander from nor to anticipate the phenomena on which his attention was fixed . . . . He was not brilliant. He made at first no great impression on those about him. He was a simple, straightforward, kindly man, who met life with equanimity and charity and tolerance; a conscientious, painstaking physician; a patient, careful, scrupulous, time-taking, thoughtful student; and in the end he stood out as one of the great figures in the history of medicine."

THE BRIGHT MEMORIAL MEDALS.

Dr. A. F. Hurst proposed the vote of thanks to Prof. Thayer for his address and, this having been recorded unanimously, he presented to Lord Balfour the following for the reception of the Bright Memorial Medal: Prof. Thayer, Prof. Aschoff, and Sir John Rose Bradford; Prof. Lemierre, representing Prof. Widal, was also presented. To each of the recipients in order Lord Balfour, in presenting the medal, made a characteristically happy speech. He thanked Prof. Thayer warmly for his presentation of a great man of science who was also a beautiful character, and recalled the fact that when he was Prime Minister it had fallen to him to recommend Sir William Osler for the Regius Professorship at Oxford, and so, in some small sense, to have been connected with Prof. Thayer's succession to Osler's position at the Johns Hopkins University. He alluded in happy phrases to Prof. Aschoff's eminence as a pathologist, warmly thanked Prof. Lemierre for coming at so short a notice to give them the advantage of hearing French contemporary wisdom, and to the President of the College of Physicians he expressed the debt of all present for his fine scientific work on various aspects of renal disease.

Dr. Hurst then stated that when the celebration of the centenary of Richard Bright's work was first contemplated at the hospital where his work had been done, the thoughts of Guy's men had turned naturally to their great fellow-student, the late Prof. Starling. Death had unfortunately intervened, but he asked Lord Balfour to entrust him, on behalf of Mrs. Starling, with the Bright Memorial Medal which the School had decided to award to her husband prior to his death.

A collection of Bright relics was on view in the Gordon Museum, while the laboratories in the Medical School were open for inspection.

THE MINISTER OF HEALTH AT BIRMINGHAM.—On July 8th Mr. Neville Chamberlain addressed the members of the College of Nursing in conference at Birmingham, incidentally remarking that it was the fifth occasion in as many weeks that he had found himself speaking on nursing matters. He took as his subject: "The place of education in the provision of a proper nursing service," but in reply to questions held out no hope that the education authorities were likely at present to be able to assist the profession with grants. He had been giving time, he said, to the consideration of a project for the establishment of a post-graduate school of medicine in London, for the benefit of practitioners from all parts of the Empire. For this there seemed an undoubted demand.

THE LISTER MEDALLIST.

PROF. EISELSBERG'S ADDRESS.

EVERY three years a Lister Medal is awarded in recognition of distinguished contributions to surgery. The award is made by a committee representing the Royal Society, the Royal Colleges of Surgeons of England, Scotland, and Ireland, and the Universities of Edinburgh and Glasgow, and this year the recipient is Prof. Anton Freiherr von Eiselsberg, of Vienna. On July 7th, after a reception, the presentation was made by Sir Berkeley Moynihan at the Royal College of Surgeons of England, of which Prof. Eiselsberg became honorary Fellow in 1913.

In an address delivered in the theatre of the College to a distinguished audience, Prof. Eiselsberg said :—

It is a special pleasure for me to see among my friends here Sir William Watson Cheyne who three years ago was the first recipient of the Lister Medal. I feel that my contribution to science has not been worthy of so great an honour and I presume that this distinction is intended to do honour to my great master Billroth. It was my privilege to be his assistant for nearly ten years, and throughout my life he has been my ideal in private as well as in professional life. Billroth worked on the problem which Lister so ably solved; his theoretical conclusions differed somewhat from those of Lister, so that he may be excused from not having adopted immediately Lister's new methods. Nevertheless, from the very beginning he had the greatest respect for the great surgical reformer and sent some of his assistants to Lister's clinic to study the new method. I am to this day grateful to Billroth for his advice to spend one of my vacation periods on a visit to King's College Hospital, for it will always be one of the most prominent impressions of my career to have personally met and seen at work the man who is recognised as one of the greatest benefactors of the world.

Surgeons of 70 and more years ago were not less clever than to-day, but they had no anæsthetics and thought primarily of technical perfection and speed in operation. We hear of the famous French surgeon, Baron Larrey, who after the battle of Eylau did, in one day, more than 200 amputations of shattered limbs, the amputation of each requiring on the average less than one minute. At that time it was necessary for all surgeons to be able to acquire this facility and my teacher, Billroth, became more clever and speedy in operating than any one to-day could ever hope to be. He could complete the disarticulation of the arm from the shoulder in less than 30 seconds. But the speed of the operation was not sufficient to guarantee that the wound would heal. Nussbaum, until 1890 director of the Munich Surgical Clinic, deplored the fact that 80 per cent. of his cases developed hospital gangrene after operation. At the beginning of the nineteenth century in the Hôtel-Dieu, at Paris, 80 per cent. of all patients with amputations of the femur died from wound infection, and between 1862–72, after 671 amputations performed in different hospitals, more than one-third of the patients died of different infections. The change that has come over surgeons to-day compels us to think highly of Lister's work.

The Revolution in Surgery.

What made Lister the hero of the scientific world was his systematic and careful investigations on living animals and the exact observations in his clinic, combined with laboratory work in the new science of bacteriology. Like John Hunter he noticed the great contrast between the healing of subcutaneous and open fractures and he bore it constantly in mind. The danger of compound fractures was acutely felt even in the great clinics where the best surgeons were working, and yet Lister, working in probably the most unhygienic hospital of all, that of Glasgow, obtained the marvellous result that out of 12 compound

fractures of the lower extremity he was able to heal nine. To-day practically nothing remains of his original technique, but the principle upon which this technique was based still holds good. The reason why he did not find that antiseptics would cure all infection was that, though far in advance of his time, he could not know the power of resistance inherent in the human body nor foresee Robert Koch's great work on bacteriology. The human body differs completely from the artificial culture medium in the Petri dish.

The Need for Caution.

Since infection of wounds has been prevented, one disease after the other has been treated by surgery. Every year has brought us new operations, and there have been times when the enthusiasm of the surgeon has prompted him to attempt too much. We have learned, for instance, that resection of tuberculous joints in children should not be performed, or at least should only be performed so that the epiphyseal line is not injured and the growth of the limb impaired. We all know the unhappy consequences of complete extirpation of the thyroid gland, and if we are now able to control them it is altogether due to experimentation on animals. By such means it was proved that the loss of the gland may be mitigated by oral feeding, subcutaneous injection of the extract, or under certain conditions by transplantation. Now, since we know that before a man's blood can be transfused into another the blood should be grouped, so we must, before making such a transplantation, apply the necessary tests. And if the famous experiment of Alexis Carrel, who successfully transplanted a kidney or an extremity from one animal to another, should ever be tried on man, the same test must be made. From the clinic of my friend and pupil, Clairmont, at Zürich, the following has been reported :—

A patient lost a large piece of skin by an accident. The wound had to be covered by skin-flaps. The "blood-number" of the patient was No. II. Transplantation was performed from three donors, I., II., and IV. All skin-flaps from No. II. healed, some healed from No. IV., but none from No. I.

Lister's goal was to remove danger from open fractures. He attained this object, but he went further. He cut down on a subcutaneous fracture which could not be reduced by manipulation—the patella—and sutured it successfully. Since the advent of Rontgen rays surgeons have sutured subcutaneous fractures more and more frequently. In my large accident ward at Vienna we treat fractures, particularly of the lower extremity, only occasionally by open suture and more often by Codivilla Steinmann nail or Schönmann-Schmerz tongs with extension. The point of this tong is introduced through the periosteum into the bone. Before the days of Lister this procedure was a dangerous one, as is evident by the results obtained from the Malgaigne clamp for patella fractures 100 years ago.

My own opinion is that some surgeons use operative methods for the treatment of fractures, and in other cases, far too frequently. Every step forward in surgery may cost life, therefore before any such step is taken one should endeavour to check results by anatomical research, physiological considerations, and by animal experiments in order that this danger may be reduced to a minimum. Especially when the operation is performed on a case, not in itself dangerous, which could perhaps be treated in another way, it is always necessary to ask "would I perform this operation on my parents, my wife, my children ?" Are we allowed to experiment on living man ? The problem presents itself also in regard to the too many sample drugs which every doctor receives daily by post. Should these be tried on his patients ?

Both Lister and Billroth published unsuccessful as well as successful cases in order that other surgeons might profit by their experience. It is a pity that all surgeons do not do likewise. Lister said, "the best thing that can be done by a man for the propagation of the truth is the correction of the faults previously committed by him." I wish that all scientists and all politicians, and in fact all classes of men would follow this golden rule.

Discriminating Surgery.

The good results obtained by Lister led to operations which are not perhaps necessary or entirely justifiable. I myself seldom perform a gastropexy nor a nephropexy. I personally cannot believe that in the majority of cases this constitutional anomaly can be healed by a mechanical operation. The less dangerous gastric operations become, the more frequently exploratory laparotomy is performed; and when no pathological symptom is found some surgeons feel that something must be done with the stomach and decide to do a gastro-enterostomy. Such procedure prejudices the beneficial results of an operation which should be productive of the best results when undoubtedly indicated. The cure may be worse than the disease for postoperative jejunal ulcers are often the sequel. Indeed, one of my pupils, Pribram, wrote a paper called Gastro-enterostomy a Disease. The surgical removal of such an ulcer is one of the most difficult operations, and even then does not with certainty prevent the appearance of a new ulcer. As a result of its indiscriminate use, gastro-enterostomy, which at one time was the most popular of gastric operations, has in recent years lost much of its popularity.

In the last 25 years we performed in my clinic 1681 operations for ulcer :—

		Per cent.
Resection ..	1102, with 59 cases of death	= 5
Gastro-enterostomy	541, „ 30 „ „ „	= 5
Jejunostomy	39, „ 13 „ „ „	= 30

The high mortality after jejunostomy is accounted for by that fact that jejunostomy is only performed in cases where neither resection nor gastro-enterostomy is possible.

Social Standing of the Surgeon.

The progress of surgery last century completely changed the standing of the surgeon. One hundred years ago the surgeon was not much more than an itinerant barber; the physician, on the other hand, with his wig, staff in hand, attended the patients, made the diagnosis, and advised the operation, which was performed by this barber who also did the blood letting and rendered other menial service. If the operation was successful it was due to the foresight of the physician, but if it went wrong it was owing to the clumsiness of the barber. During the last 60 years the surgeon has had the same fundamental training as the physician, and gradually he has risen to the same social level; throughout his career Lister was very much concerned about raising the surgeon's position. Concomitantly with the rise of status of the surgeon came the rise in that of the nursing organisation. It is not a matter of chance that the teaching of nurses in England is of the highest order; it is due to early inculcation of the feeling of responsibility.

Antiseptics.

The great majority of operative wounds now heal without any complication. However, in some cases —all surgeons know that—complications will appear. The aseptic method is not sufficient, especially where it is necessary to operate in infected surroundings. The great war reawakened by necessity the interest in old as well as in new antiseptics, and the old antiseptic treatment of Lister was new-born.

A doctor who was completely misunderstood by his colleagues, an assistant in the gynæcological clinic in Vienna, Ignaz Philipp Semmelweis, recognised in 1850 that puerperal sepsis was due to unhygienic conditions caused by the failure of doctors and students to clean their hands thoroughly before examining their patients. He proposed washing in calcium chloride solution, but unfortunately his colleagues would not support him. Only many years after his death the truth of his teaching was recognised. There has often been a discussion whether Lister or Semmelweis was

the father of the modern treatment of wounds. This discussion is superfluous. Let us be happy that two men independently had this epoch-making idea. The principles put foward by Semmelweis were not accepted by his contemporaries, but those advanced by Lister gave a tremendous impetus to the study of antisepsis. It was only about 1888, more than 20 years after his own discovery, that Lister heard of the efforts of Semmelweis and was full of admiration for him.

An antiseptic which kills bacteria without injury to the body-tissue does not exist. But the study of and experiment with serum have shown great therapeutic possibilities. Perhaps some day we shall have a polyvalent serum, which can protect us against all pathogenic organisms. This would render all our present methods of asepsis unnecessary and would simplify to the last degree all our operative precaution. I will no longer dwell on such dreams.

The Problem of Cancer.—Euthanasia.

In my clinic there have been made in the last 25 years 376 resections of cancer of the stomach, and in 70 of these cases the patients died after operation, though I must state that this has sometimes been very radical. We have performed gastro-enterostomy in 417 cases with 58 deaths after operation, 95 jejunostomies with 42 deaths, and 294 exploratory laparotomies with 28 deaths. All these cases show us that patients consult the physician too late. The mortality of jejunostomy, which is the quickest and easiest operation, in my clinic is due to the fact that these operations are only done when obstruction occurs, making it inadvisable to perform radical resection or gastro-enterostomy. As the above will show, out of 1182 cases of cancer of the stomach which have been operated upon, resection could be done in only 376. These statistics indicate that since we have no better method at the present time our greatest hope is that we shall be able to teach the young physicians the necessity of the early diagnosis of cancer. When one considers that 18 per cent. of all cases died immediately after the radical operation, and 58 per cent. of the surviving 82 per cent. died from recurrence within the first year, it is absolutely clear that a new remedy is necessary to give us mastery over the disease. A cancer early recognised and early cut out is often radically healed.

Here comes the question: Shall I tell the patient that he is suffering from cancer? I think we cannot give a general rule. I personally follow the example given by Billroth, not to tell the patient directly that he is suffering from a cancer; but I never fail to tell the facts to some responsible member of his family.

In special cases it is necessary, of course, to tell the patient, not only that he requires an operation, but also the extent of the operation, and if the patient or his family refuse the operation it must not be performed, however definitely indicated. To-day, however, we have scarcely to mention that an operation is necessary, for patients demand them even against our advice. Particularly is this true in *cosmetic* operations.

Another question interesting to the medical man is whether under any circumstances he is justified in shortening the life of a patient suffering from an incurable and perhaps agonising illness. Setting aside all religious and worldly considerations and looking at the problem from an ethical standpoint alone, I may at once say that a doctor would never be justified in doing so. Diagnosis is not yet sufficiently exact.

The Story of Progress.

It is the experience of all surgeons engaged in abdominal surgery that sometimes a case presents itself which on exploratory laparotomy is inoperable and appears to be incurable. The operation wound is closed, the worst prognosis is given, and the patient gets well! What is to-day an incurable disease may to-morrow be curable. Galen long ago spoke of three especially painful and incurable diseases: neuralgia of the trigeminus, ulcer of the stomach, and stone of the bladder. All these are now curable.

Generations come and go. Only the work performed remains. Before medical science had reached its present high level an immense amount of plodding research had to be gone through, untold nights spent in watchful medication, numberless sacrifices of pleasure and indulgence made. Of all this how little remains alive in the memory of posterity! The world knows nothing of the silent performances of duty which the working of our everyday life demands by day and night. The general country doctor, the medical practitioner in the town, have one and all their special sphere of action. They go through life and the noisy world does not heed them. But all these thousands of springs feed the life of the one man, who is destined to be the leader of a new era.

PRESENTATION OF THE MEDAL.

Sir Berkeley Moynihan, in presenting the Lister Medal, referred to the Vienna Surgical School as "the intellectual home of many of us before the war." Prof. Eiselsberg would be the first to feel glad that in paying a tribute to himself they were also paying tribute to Billroth. Something of the spirit of a teacher passed on from generation to generation. Billroth had trained eight occupants of chairs of surgery in Europe, and so far Prof. Eiselsberg had himself trained three; Sir Berkeley Moynihan hoped that in the years to come he would equal the record of his master. But it was not only as a distinguished contributor to surgical science and as a teacher that Prof. Eiselsberg deserved the honour being paid to him; he had done something more; he had raised the standard of conduct in his school and elsewhere. Not only a great practitioner and a great teacher, he was also a great example to all who practised the art of surgery, and it was fitting to associate his name with that of Lister by placing it upon the roll of those to whom the Medal had been awarded.

BRITISH EMPIRE CANCER CAMPAIGN.

ANNUAL REPORT.

THE British Empire Cancer Campaign is now well in its stride. The imposing format of its fourth annual report, presented at a meeting held at the House of Lords on July 11th, is more than justified by the wide range of the activities recorded. The objects of the campaign are clearly defined. Apart from the ultimate ideal of discovering the cause of cancer and the means of curing or preventing it, the secondary aims to which efforts are being directed are—

(1) The maintenance of existing cancer research centres at their maximum efficiency by financial assistance.

(2) The encouragement and establishment of new cancer research centres in association with universities and medical schools and the development of new schemes of cancer research.

(3) The financial support of individual cancer research workers under approved conditions.

(4) The coördination of cancer research generally.

The total amount of money expended on research, including commitments, now exceeds £125,000.

The Plan of Campaign.

Special centres of research have already been established in connexion with the Universities of Leeds and Birmingham, and negotiations for the granting of subsidies to corresponding schemes in Manchester and Liverpool are being carried on. Affiliation of the newly formed National Cancer Campaign for Ireland and of the independent movement started in the University of Sydney to the British Empire Campaign has been arranged. The publication monthly of the *Cancer Review*, wherein the enormous world literature relating

to cancer is abstracted, also serves to enable workers in different countries to keep in touch with progress made and to save their time, since they need refer to the originals only of those papers which are directly relevant to their own work.

The detailed work of organisation of the Campaign is largely entrusted to seven committees—notably the Scientific Advisory, Executive, Preliminary Inquiry, Intelligence, Management of the Journal, Radiology, and Finance Committees. In submitting the record of the year's progress the Council explains that these committees assume no scientific responsibility for statements of fact and opinion contained in the reports, compiled by the institutions and individuals in receipt of grants, which form the bulk of the annual report. The institutions subsidised include the Cancer Hospital Research Institute, the Cancer Research Departments at the Middlesex Hospital, St. Bartholomew's Hospital, St. Mark's Hospital and the Christie Hospital, Manchester, the Medical Research Council Radon Centre at the Middlesex Hospital, the London Association of the Medical Women's Federation, the Tropical Disease Prevention Association, the Westminster Hospital, the Coombe Lying-in Hospital (Dublin), and the Birmingham University Cancer Research Centre. Other grants have been made in connexion with radium research and whole- or part-time grants have been made to 12 individual workers. Many of the observations here recorded have been published in full in our columns, notably those of Dr. T. Lumsden, Prof. S. Russ and Miss G. Scott, Dr. J. C. Mottram and Dr. R. D. McKenzie, and Mr. C. F. W. Illingworth; we select for notice here some of the hitherto unpublished indications of the progress of work.

Tumour Therapy; Colloidal Lead.

As the outcome of a visit paid to Liverpool in October, 1926, by six delegates from the Campaign, it was decided that there was a good prima facie case for the continuance and extension of the work initiated there by Prof. Blair Bell on lead in the treatment of cancer. Arrangements are now in train for assistance to be given to the Liverpool organisation in raising further funds for their researches when this becomes necessary, and a grant has been made to St. Bartholomew's Hospital Medical College to enable further independent researches to be carried out on similar lines; the treatment is also being studied at the Christie Hospital in Manchester.

At the Cancer Hospital Research Institute, in autopsies on eight cancer patients who died during treatment by colloidal lead preparations no evidence was found suggesting any destructive change in the cancerous tissue or any arrest of the process, but some normal vital organs had suffered damage. The kidneys always showed extensive tubular degeneration, the liver commonly showed focal necrosis with advanced fatty change; in some cases cerebral œdema and thrombosis of the vessels of kidney and liver were observed. These observations and the results of lead treatment will doubtless be published in due course.

In Birmingham an inquiry, chemical, experimental, and clinical, into the value of colloidal lead compounds in the treatment of cancer is being pursued. The material received for testing proved to be too toxic for safe use; Mr. Saunders, M.Sc., a research chemist, was appointed to assist in the work and is preparing colloidal compounds of lead which are less toxic and may prove more stable. Clinical work, suspended until a satisfactory form of the drug should be discovered, is being recommenced.

Various alleged remedies, such as substances containing tartar emetic and violet extract, have been tested out at the Middlesex Hospital with negative results as far as specific action on tumour growths is concerned; some of these possessed a powerful local caustic effect. At present a number of chemical substances, including different preparations of lead, are being tested for toxicity and curative properties.

Rous Chicken Sarcoma.

Much work has been stimulated by the researches of Gye and Barnard on the Rous sarcoma. At the Middlesex Hospital Dr. S. L. Baker has confirmed Gye's experimental facts in that an activating effect has been obtained from broth cultures of the mammalian tumour (Jensen's rat sarcoma); it has not been possible to obtain activation with more remote subcultures from such broth. This research, while supporting much of the experimental work of Gye, and particularly that part played by accessory factors, has not afforded any conclusive evidence that the activating agent obtained from the mammalian tumour is a living virus. Workers at the Cancer Hospital say that such evidence as they have does not support the virus theory. Extending the work done by him jointly with Dr. McKenzie, Mr. Illingworth with Dr. Alexander found that neither of the factors postulated by Gye was able to withstand exposure to ultra-violet rays.

Workers at the Middlesex Hospital, testing quantitatively the lethal effect of ultra-violet light on the infective agent, found that the Rous agent is about five times as resistant as ordinary bacteria. The discovery at this hospital that the addition of a ferment (trypsin) and also the alteration of hydrogen-ion concentration has a marked effect on the virulence of the sarcoma filtrate is regarded as a most important development, which may have a wide application to the pathology of tumours. It is possible by adjusting these factors either greatly to increase or completely to inhibit the development of the fowl sarcoma.

Sero-diagnosis of Cancer.

Prof. E. C. Dodds and Mr. W. Lawson find that the Interferometer method is entirely unsatisfactory as a method of diagnosing carcinoma. At Cambridge Dr. G. S. Haynes has not obtained uniform results with this apparatus—in some cases striking success having been achieved, in others a complete lack of correlation. The possibility of the development of some serological test for cancer of the bowel has been one of the principal lines of investigation at St. Mark's Hospital. At Westminster Hospital experiments aiming at the evolution of a complement-fixation test for cancer were abandoned only after considerable trial; attempts to confirm Shaw-Mackenzie's test led to the conclusion that since a positive result can so often be obtained in conditions other than cancer, this test is valueless as a specific reaction for malignant disease. Attempts are being made by Mr. F. C. Pybus at Newcastle to use the method of complement fixation among others in the further investigation of the possibility of producing an immune serum against malignant cells.

Radiological Investigations.

The dosage of X rays or radium which is necessary to prevent the growth of tumours is one of the subjects of experimental study at the Middlesex Hospital, also the reaction to irradiation of the blood and of normal tissues surrounding the growth, and the nature of the immunity produced by inoculation of small quantities of X rayed tumour. A new installation for the production of X rays of short wave length will, when preliminary physical measurements and animal experiments have been undertaken, be used for research into the changes produced by X rays in the function and structure of both normal and cancerous tissues. At the Cancer Hospital complete blood counts made in 222 cases of malignant disease under deep X ray treatment revealed no striking abnormality due to the radiations. Similar negative results are reported from the Coombe Lying-in Hospital, Dublin. At the Radiological Cancer Research Department at St. Bartholomew's Hospital 59 patients were treated during 1926, 49 in 1925. The tentative conclusions drawn from this material as to the early results of deep X ray therapy are that there is a considerable difference in the response of malignant disease in different regions to X ray treatment. Whereas in malignant disease of the uterus the response is decidedly encouraging, in the breast group it is only slightly less so, while œsophageal and rectal cases give unsatisfactory results. In the upper air passage group it is noteworthy that while of 37 cases treated in the two years 29 were microscopically squamous-celled carcinoma; of the six cases reported free from signs of the disease only one was a squamous carcinoma. From Birmingham a corresponding group difference is recorded in connexion with radium, mouth cancer responding well and rectal cases badly to treatment.

The London Association of the Medical Women's Federation report that 117 cases of uterine cancer treated by radium have been given a dose of approximately 7000 m.e.h. within three weeks. No mortality was directly due to the treatment. Many of the cases were very septic before treatment and in eight there was pyometra; with the preparatory technique now used the treatment is only rarely associated with rise of temperature. Great benefit is said to have resulted even to quite hopeless cases.

Dr. Malcolm Donaldson describes the method whereby a cinematographic study of the behaviour of embryonic cells and of cells from malignant tissues grown in vitro has been prepared by Dr. R. G. Canti. This apparatus will be used to study the laws governing the disappearance of malignant growth under the influence of beta and gamma radiation; the effect of beta radiation on the cells is markedly to inhibit the cell movements. On the clinical side Dr. Donaldson reports that 50 mg. of radium element used over a long period has been the technique employed by him; he

believes that in the future even more prolonged doses will be used, especially in those tumours, such as carcinoma of the vulva, where the resistance to irradiation seems to be very great.

Conclusion.

The Council may justly claim that the impetus given to research work into the causation and treatment of cancer continues to gather weight. More and more workers are coming forward, and the results already recorded are being subjected to searching criticism. In certain directions observations are being extended and amplified in laboratories other than those in which they originated. This careful following up of clues or hopeful suggestions involves considerable expense. The funds are being administered with the utmost economy consistent with exploring every possible avenue of approach to the cancer problem, but the expenses are necessarily heavy. The Council work on the principle that no claim to have discovered anything important that may have a bearing on the cure or prevention of cancer is to be turned down without careful investigation; that no appeal for assistance is refused without consideration by those most competent to judge of the possible value of the work contemplated, and that support is given to any research that seems likely to have a bearing on cancer. At the same time money is not wasted in the subsidy of researches which have already been proved useless, and undue overlapping of allied investigations is discouraged unless cumulative evidence on any point is desired. For these reasons, being confident that the Fund is distributing the money at its disposal in a wise manner, we cordially support its appeal for further munition for the active prosecution of this greatest of all wars.

MEDICINE AND THE LAW.

Professional Secrecy and Venereal Disease Clinics.

IN the discussion which followed the delivery of Lord Riddell's address on "The Law and Ethics of Medical Confidences" before the Medico-Legal Society on June 23rd, mention was made of the special obligation of secrecy imposed by regulations under the Public Health Acts upon all concerned in the conduct of venereal disease clinics. This special obligation is to be found in Article II. of the Public Health (Venereal Diseases) Regulations of July 12th, 1916. After directing county councils and county borough councils to prepare and submit schemes for venereal disease treatment at local hospitals and other institutions, and for the supply of salvarsan and other remedies to medical practitioners, Article II. continues: "All information obtained in regard to any person treated under a scheme approved in pursuance of this Article shall be regarded as confidential." It might be possible to suggest—as is suggested by Lord Riddell in a letter published in another column—that this special statutory duty of secrecy would override the judicial power to compel a medical witness to disclose confidential matters affecting his patient. On the other hand, the wording of the article is drafted rather as a general instruction than as an absolute prohibition of disclosure; no penal consequences are laid down for violation of this particular regulation or any other of this set of regulations. It is as though the Local Government Board, when issuing its administrative orders in 1916, desired to establish the essential atmosphere of confidence, but did not contemplate the necessity of penal enforcement. It is unlikely that a judge would allow a medical witness to rely upon Article II. as imposing a statutory duty of silence in the witness-box. Indeed, there has already been a judicial ruling upon the point. In the divorce case of Garner *v.* Garner (reported in the *Times* of Jan. 14th, 1920) a medical witness drew the judge's attention to this passage in the Venereal Diseases Regulations, but the judge ruled that the witness was nevertheless bound in law to answer the questions addressed to him. This case was, however, peculiar in that the doctor was called to give evidence on behalf of the patient and at her own request. Professional secrecy being a one-sided duty owed by doctor to patient, the patient can at any time release the doctor from the duty. The relationship between solicitor and client provides a parallel here. The instructions given by client to solicitor are absolutely privileged; no court can compel the solicitor to disclose a single word of them. Yet if a litigant is challenged upon any matter which he can establish by the evidence of those instructions (for example, proof that he was making a particular claim at an early stage in the proceedings), the solicitor might be put into the witness-box to prove the point. The obligation of professional secrecy can be waived if disclosure is more advantageous to the client than secrecy. The lesson of Garner *v.* Garner, therefore, is that the duty of non-disclosure under the Venereal Diseases Regulations is not absolute; the situation is still governed by the old ideals of professional tradition. The position remains that the doctor is denied in a court of law the complete professional privilege which is allowed to the solicitor, but that he must do his best upon a proper occasion—by protest, appeal to the judge or any other legitimate means—to claim the utmost possible degree of privilege for the communications which have passed between his patient and himself. Courts of law might be reminded that the Royal Commission on Venereal Diseases recommended that treatment should be so organised that persons suffering from these diseases should not be deterred from taking advantage of the facilities provided. The Local Government Board circular which accompanied the issue of the regulations in 1916 rightly stated that it was essential for the success of any measures designed to deal with venereal diseases that patients should be fully assured as to the secrecy of the arrangements. Each patient attending for diagnosis or treatment, observed the memorandum of the Board's medical officer, should be assured that, though his home address will be kept confidentially for reference, it will never be communicated to others. Lord Trevethin's Committee of Inquiry into the Prevention of Venereal Disease in the Civil Community reported in 1923 that the present principle is, by maintaining secrecy, to encourage sufferers to come to treatment and to continue treatment, "and we think that in the present state of public opinion any system of general compulsory notification of venereal disease would tend to concealment and would prove a backward step."

The mention of compulsory notification leads to another reflection. If venereal diseases became compulsorily notifiable, an immense breach would have been deliberately made in the rampart of professional secrecy. The step would be so serious that it may confidently be assumed that the Ministry of Health would not make it by way of departmental regulations under the Public Health Acts, but would obtain the express direction of Parliament. And at this point it must not be forgotten that already Parliament has made venereal diseases notifiable to a limited extent locally. The Bradford Corporation Act of 1925 (15 & 16 Geo. 5, cxxi. s. 68) gave five years' trial to a clause making venereal disease an infectious disease within the Infectious Disease (Notification) Act of 1889 in the following circumstances—(*a*) in the case of infant patients under 2 years of age, and (*b*) in the case of a patient (not being a child) who, after being informed by any medical practitioner attending on or called in to visit him, or by the medical officer, that further treatment is necessary in order to effect a cure of such disease, refuses or neglects to undergo such further treatment. This provision was an attempt to deal with the "defaulting" patient, for whose "following-up" local arrangements (by using the services of nurses, almoners and others) have been devised with varying degrees of success. If legal proceedings

have to be taken under the Bradford Corporation Act, the confidence of the venereal disease patient is violated and the professional tradition is impaired afresh. It should perhaps be noted that the obligation of secrecy is not confined to the medical practitioner alone. It extends to, and is honourably accepted by, others—students, nurses, and the officials of local authorities. The organisation of venereal disease clinics widened the obligation of non-disclosure; this circumstance in itself might justify and explain the reminder in Article II. of the Regulations of 1916.

Probate Action by the London Hospital.

The governors of the London Hospital had lately to bring a probate action in circumstances in which they got no profit for themselves but were (in the language of the President of the Probate and Divorce Court) performing a public duty. A lady died on April 24th, 1925, aged 42, leaving about £2200. By a will executed in 1914 she had made the governors of the London Hospital her residuary legatees, but this will could not be found. Mention was made during the action of three other wills alleged to have been subsequently made by her—one of Oct. 17th, 1921, another of April 16th, 1925, and a third of April 21st, 1925. Under this last alleged will, purporting to have been made three days before her death, a Mr. Martin Harcourt Waters, residing at Salisbury and engaged to some extent in estate management, was appointed sole executor. Mr. Waters had been well acquainted with the testatrix for many years, certainly from 1921 to 1925; on her death he proceeded to obtain probate of the alleged final will of April 21st, 1925. But, according to the findings of the President, the signatures of the witnesses to the document were not written by the persons whose names appeared thereon; they strongly resembled the writing in the body of the document. The signature of the alleged testatrix might have been hers or not; if not it was a carefully prepared imitation. The testatrix had become a drug addict. Medical evidence was given that she suffered from chronic Bright's disease and from injections of morphia for many years. She was comatose and moribund in the spring of 1925 and incapable of carrying out any testamentary act or of understanding its purport. The London Hospital put forward the will of 1914 as a valid and subsisting will at the time of the lady's death; they asked the court to revoke the probate which had been granted in respect of the supposed will of April 21st, 1925, and to pronounce for the lost will of 1914. They said the will of April 21st, 1925 (under which Mr. Waters became sole executor and beneficiary), was not duly executed; that the lady did not know or approve of its contents, and that she was not of sound mind at the time it was executed. Mr. Waters put in a defence, but apparently did not appear at the trial of the action, and was not represented. He said the 1914 will was revoked by the will of 1921, which in turn was revoked by the will of April 16th, 1925, itself revoked by the final will made five days later. The President pronounced against all the three wills set up by Mr. Waters, but felt unable to pronounce in favour of the 1914 will since there was a good deal of evidence of revocation of that will by subsequent testamentary acts. The upshot of these findings was, it seems, that the lady was held to have died intestate. In effect the London Hospital had charged Mr. Waters with fraud. On this issue the President found it unnecessary to pronounce, but he found against Mr. Waters with costs, and ordered the papers to be sent to the Public Prosecutor. The London Hospital came forward in this matter not because it expected to recover anything (indeed its counsel remarked that it was doubtful if there was any money left to be recovered), but out of a sense of duty to expose certain remarkable facts. Lord Merrivale, as already stated, complimented the hospital upon its public-spirited action.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Suicide in Germany.

THE belief that suicide has increased in frequency since the war is apparently mistaken. According to a recent statistical record the number of suicides per 100,000 persons was as follows:—

1888–90 ..	20·6	1911–13 ..	21·8	1920 ..	21·7
1891–1900 ..	21·4	1914 ..	20·9	1925 ..	21·5
1901–10 ..	22·4	1915–19 ..	16·9		

Apart from war-time, when for obvious reasons there was a decrease, the average number of suicides has been about the same for nearly 40 years. Generally the incidence is greater in towns than in the country. In the Rhenish provinces—Westphalia, Upper Silesia, and Bavaria—where Roman Catholics predominate, the number of suicides is only a third of the number in Berlin, Hamburg, and Saxony. It is a very striking fact that the percentage among women has considerably increased; whereas in 1890 only 26·3 per cent. of suicides were committed by women the percentage had increased by 1924 to 48·6. Forty per cent. are ascribed to mental troubles, only 7 per cent. to economic causes, and 33 per cent. to grief, whilst in 20 per cent. the cause is regarded as unknown. In 1924 as many as 104 children under 15 years committed suicide in Germany. Of other countries France, Switzerland, Japan, Austria, and Hungary have about the same suicide-rate as Germany, but in Denmark and Sweden it is less by one-third, whilst in the United States, England, Belgium, Norway, and Spain it is less by one-half. In Italy and Holland the number of suicides per 100,000 is only one-third of that in Germany, and it is said that the lowest figures are recorded from Bulgaria and Ireland.

An Unusual Crime.

A trial unique in the history of the medical profession lately took place before a criminal court in Cologne, where a medical man was prosecuted for murdering a patient with whose wife he had had illicit intercourse. The facts as stated were very peculiar. The victim, an architect, had suffered from heart disease, and was attended at home by the accused. His state by and by became worse, and the doctor had him conveyed to a hospital where he had been an assistant physician before settling down as a medical practitioner. Here he was able to see the patient frequently, with the consent of the hospital staff. At the trial it was alleged that the accused had told the patient that he was suffering not only from heart disease, but also from syphilis, and had recommended him not to inform the hospital physician of that fact, as he would himself cure him of the disease by injections given without their knowledge. To this the patient agreed, being unwilling, out of shame, to reveal his condition. When he went to hospital his condition at first improved, but after a few days he got worse and suddenly he died with gross albuminuria, hæmorrhage from the bowels, and general collapse. At the post-mortem it was discovered that death was due to mercury poisoning. The peculiar behaviour of the accused led to suspicion that he had caused the illness, for when the result of the autopsy was made known he fled to Amsterdam with the wife of the deceased. They were discovered there by the police before they could escape to the Dutch colonies, as had been their intention, and were brought to trial at Cologne. At the trial it was stated in evidence that the doctor had frequently given injections to the patient without the knowledge of the hospital physician. He had insisted that the patient should have a room of his own in the hospital, although he was scarcely in a position to pay for it. Death had occurred after an injection of novasurol, a strong mercurial preparation, of which he had given ten times the usual dose. The accused, however, pleaded not guilty; he denied that there had been any adultery

and counsel pointed out that if his client had wanted to kill the patient he could easily have done it at his home, instead of having had him conveyed to hospital for the purpose. The public prosecutor claimed that the doctor had been induced to commit the crime by the patient's wife, and that the two were equally responsible. After a trial lasting three days the jury brought in a verdict of Guilty and both the medical man and the wife were sentenced to death.

Patent Medicines.

The President of the Apothecaries Association lately stated in the *Deutsche Medizinische Wochenschrift* that the list of patent medicines in tablet form kept by the Association includes not less than 20,000 preparations, and there are about 5000 more which are not to be found in the list. A chemist of Freiburg University has undertaken to examine the composition of the patent medicines and has ascertained after 5000 tests that large numbers of the compounds are practically identical. Often the name of the drug alone was changed. The need for legislation in this matter has been recognised, and in an official statement on behalf of the Government it is stated that at present no control is exercised over the quality and uniform composition of patent medicines, the only safeguard being the reputation of the manufacturer. The existence of too many of these preparations, it is remarked, encourages the profession to more schematic treatment, induces the public to cure themselves instead of consulting a medical man, and facilitates secret and illegal traffic in drugs. A new Bill will provide for control of the production of patent medicines within the chemical works and for the issue of licences to import such compounds from abroad.

Synthalin.

Before the Society for Internal Medicine Prof. Umber, of the West End Hospital, recently read a paper on his results in the treatment of 200 cases of diabetes by synthalin. His experience showed that synthalin is not useful in coma, that undesirable complications occur rather frequently, and that administration of the remedy has therefore to be interrupted from time to time. With synthalin the amount of sugar is reduced in the urine, but not in the blood; tolerance to carbohydrates is increased. Prof. Umber recommends that the drug should be given every other day, together with insulin. The quantity of insulin is gradually reduced and eventually synthalin alone is used. Insulin, he considers, continues to be the remedy par excellence for diabetes.

Artificial Pneumothorax.

At a recent meeting of the Leipzic Medical Society Dr. Fischer reported the results obtained in the Leipzic Medical Clinic in the treatment of pulmonary tuberculosis by artificial pneumothorax. In 60 per cent. of the 119 cases treated the opposite lung was healthy, whilst in 40 per cent. it was slightly affected. In 22 cases infection spread to the other lung during treatment, which was accordingly interrupted. The results were that 30 per cent. were cured, 22 per cent. were improved, in 8 per cent. the condition was unaltered, 17 per cent. became worse, 19 per cent. died, and in 4 per cent. no informatian could be obtained. In 52 per cent. the patients were able to work again. The puncture method was exclusively used; the patients had to stay two or three days in hospital, after which the refills could be done in the out-patient department.

INDEX TO "THE LANCET," VOL. I., 1927.

THE Index and Title-page to Vol. I., 1927, which was completed with the issue of June 25th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

"Audi alteram partem."

THE LABELLING OF EGGS.

To the Editor of THE LANCET.

SIR,—The Sale of Food Order, 1921 (Labelling of imported produce—Eggs), which is a remnant of "Dora," has been renewed each year by the Expiring Laws Act. Its administration falls upon the Public Health Departments, which also administer the Sale of Food and Drugs Acts throughout the country, and in view of the Committee of Enquiry which is at present considering the marking of eggs it may not be without interest to the many medical officer readers of THE LANCET to have a review of the situation as it has affected a large borough.

The Order provides that: "A person shall not sell or offer or expose for sale, whether by wholesale or retail, as fresh eggs or new laid eggs, or under any description of which the words 'fresh' or 'new laid' form part, any eggs which have been imported into the United Kingdom unless the description also includes the word 'imported' or word or words disclosing the country of origin."

It will be noted that it is no offence *under this Order* to label foreign eggs simply "English," omitting the words "fresh" or "new laid," and we have known this to be done. The provisions are by no means easy to administer owing to the difficulty of proof, and it would appear as if this Order, as far as it relates to eggs, has been found to be unworkable by most authorities. I say this with all due respect to those who have made some effort in endeavouring to have foreign eggs correctly labelled in their areas. As far as one can judge from cases reported in the public press, prosecutions regarding eggs under this Order are very few. I find on referring to our records in Islington that since the Sale of Food Order, 1921, has been in force 80 summonses to date have been taken out. Of these, only two were dismissed, and fines and costs amounting to £188 10*s.* 6*d.* were imposed.

Some interesting points have come out through the proceedings taken. Three of the cases were against wholesale dealers, as we refrained from taking action against the retailer who had been misled in his purchases. In another case, a purchase was made of eggs which were unticketed, but the inspector distinctly asked for "new laid eggs," and no mention was made of the fact that the eggs were imported. The defendant's manager and assistant, both at the time and in court, maintained that no offence had been committed as no written label had been used. With the remark that the defendant had been too clever, the magistrate convicted. In other cases, the word "Imported" has been written on the back of the label, or else in small letters at the foot so as to be concealed by the eggs.

In Islington this work, with the exception of two prosecutions, has been undertaken with other duties by one inspector only. In addition to these prosecutions there have been innumerable verbal warnings, and a great many letters written to offenders. It has been found that when a new tradesman moves into Islington, until he is warned he adopts the slack methods bordering on, if not actually wilfully deceptive which he has utilised, in the place he has come from, without check. We have thus forced upon us in Islington the practical futility of the provisions of this Order if they are not to be generally enforced on our borders.

Proof is, as I have stated, often a difficult matter, and has to be obtained by indirect means—e.g., the invoicing of the eggs to the retailer as imported, and the knowledge that these same imported eggs have been incorrectly described according to the provisions of the Order. Undoubtedly, not only are eggs misdescribed, but frequently foreign and home eggs are mixed. The difficulty surrounding identification of the foreign egg could be overcome if each foreign egg were required to be marked, before importation,

in some simple manner. This would prevent deception, or at least provide the means of identification if wrongly labelled, or if mixed with home produce. When one considers the number of warnings that have been issued in Islington and the number of successful prosecutions, one cannot conceive that the tradesmen in other places are more particular in carrying out the provisions of the Order. The effective remedy would appear to be, as I have said, an efficient but simple system of marking before importation. This would be simpler than the method of distinguishing home produce by marking which was advocated in a letter to the *Times* of Feb. 8th, 1926, from a Sussex writer.

In my opinion it is quite practicable to stamp eggs with a simple letter "I" for "Imported," or a small star, which would denote a foreign egg. I am sure our experience in Islington of the difficulties which surround the administration of this Order must have been experienced throughout the country, and it would be interesting to have the experiences of other medical officers of health. It seems useless to go on from year to year with this practically unworkable Order under the conditions which I show to exist.

I am, Sir, yours faithfully,

G. CLARK TROTTER, M.D., F.R.S. Edin.,
Medical Officer of Health, Metropolitan Borough of Islington.
Municipal Buildings, Upper-street, N., July 9th, 1927.

DIPHTHERIA IN LONDON.

To the Editor of THE LANCET.

SIR,—I have read Dr. Graham Forbes's letter with much interest. Since both of us have based our figures on the official returns of the Registrar-General, he and I are bound to be in agreement as to the facts. I am well acquainted with Dr. Forbes's valuable report, and my letter was not directed to anything there stated, but to the sentence in your leading article of June 11th, where you say: "his (Dr. Forbes's) figures show the incidence and mortality of diphtheria to be higher in London than in any other large city in Great Britain, and higher than that of almost any other European capital." This I consider does less than justice to the London of to-day. My letter proved that London and West Ham had the lowest diphtheria case death-rates during the past five quarters of any town in England with more than 300,000 inhabitants, and Dr. Forbes corroborates this finding.

It is quite true that an average of 15 years shows London to be in a low position, but such average does not give a correct, or even a fair indication of the treatment of diphtheria in London to-day, as is proved by the figures in the last table of Dr. Forbes's letter. No allowance for uncorrected returns can possibly, in my opinion, depose London from its high position on that table. With reference to the large foreign cities, I quoted only the figures for the first quarter of 1927 for the reason that the Registrar-General's returns do not give figures continuously during 1926 for all of the cities mentioned, and I had no means of procuring the missing figures except by worrying some official in the Registrar-General's office, which I was reluctant to do.

My sole interest in this matter lies in making it clear to the medical profession that the diphtheria situation in London to-day is not quite so black as you (no doubt unintentionally) painted it.

I am, Sir, yours faithfully,

London, W., July 9th, 1927. THOMAS MABEN.

*** Our readers now have before them the figures which will enable them to assess the degree of blackness for themselves.—ED. L.

MEDICAL CONFIDENCES.

To the Editor of THE LANCET.

SIR,—Since delivering my address to the Medico-Legal Society, published in THE LANCET of July 2nd (p. 4), my attention has been directed by Sir William Collins to the regulations regarding centres for the treatment of venereal disease. The Public Health (Venereal Diseases) Regulations, dated July 12th, 1916, issued by the Local Government Board, predecessor of the Ministry of Health, to local authorities contain the following instruction:—

Article II. (2). All information obtained in regard to any person treated under a scheme approved in pursuance of this Article shall be regarded as confidential.

A memorandum was also issued by the Local Government Board which contained the following statements:—

"It is essential that each patient attending for diagnosis or treatment should be assured that, although his home address will be kept confidentially for reference, it will never be communicated to others. The desirability of having the home address in order to be able to arrange subsequent appointments should be explained to the patient."

"At an early visit the patient's name and home address should be noted confidentially and kept separate from his clinical record. It should be explained to the patient that the home address will under no circumstances be used except for confidential communications to the patient himself respecting his treatment."

Obviously these provisions create special conditions regarding patients attending venereal disease clinics, and may impose legal obligations or secrecy upon the local authority and its medical and other servants. How the regulations would affect disclosure in the witness-box is doubtful. They purport to be made under statutory powers. Consequently, if the regulations were *intra vires* it might well be contended that statutory secrecy had been established. But however this may be the ethical position is plain, both for doctors and laymen engaged in work at such clinics.

I am, Sir, yours faithfully,

July 5th, 1927. RIDDELL.

SULPHUR METABOLISM.

To the Editor of THE LANCET.

SIR,—In a recent article (THE LANCET, June 18th, p. 1283) Dr. A. P. Cawadias suggests that in arthritis deformans there is a definite deficiency of thiopexy—i.e., an increased sulphur katabolism. It may be of some interest to your readers to compare his results with those obtained at the Devonshire Hospital, Buxton, with various rheumatoid conditions. 42 cases gave the following results:—

Total nitrogen / Total sulphur ratio.	Cases.	Total nitrogen / Total sulphur ratio.	Cases.
7·6–10·0	4	17·6–20·0	2
10·1–12·5	6	20·1–22·5	0
12·6–15·0	24	22·6–25·0	1
15·1–17·5	4		

My figures for normals vary from 11·5–15, values that accord with those found by other workers and with the figure given by Dr. Cawadias in the second paragraph of his article. In his own experiments Dr. Cawadias obtained TN/TS ratios in controls of from 1 : 7 up to 1 : 10, which suggest that either the diet used was abnormally rich in sulphur or that the Salkowski method of estimating total sulphur in urine gives higher results than the Folin process with Benedict's oxidising reagent.

I am inclined to the opinion that there is more in Dr. Cawadias's original suggestion regarding deficient oxidation than in his latter one as to excessive sulphur katabolism. If, as Folin has suggested, the neutral sulphur of the urine is endogenous in origin and is fairly constant in amount, it is necessary to consider the excretion of this moiety in terms of grammes per diem and not as a percentage of the total sulphur unless the latter is maintained at a constant value. My figures for the neutral sulphur in the urine of the same 42 cases are:—

Neutral sulphur as SO_3. Grammes per diem.	Cases.	Neutral sulphur as SO_3. Grammes per diem.	Cases.
Under 0·10	4	0·41–0·50	3
0·11–0·20	8	0·51–0·60	1
0·21–0·30	11	0·61–0·70	0
0·31–0·40	14	0·71–0·80	1

If the maximum value for normals is taken as 0·30 g. per diem the above figures indicate that

rheumatoids show a tendency towards deficient oxidation, but more proof is desirable as to the amount of neutral sulphur excreted by normals. In this respect, as with many other aspects of the rheumatoid problem, the difficulty lies in obtaining controls that are really comparable as regards age. The recent work at Ancoats showed that glucose tolerance decreased with increased age, and it is not improbable that other functions may be effected in a similar manner. As most of the controls used in work on neutral sulphur excretion are young students, deductions made from a comparison of such normals with the figures given by a much later age-group should be extremely guarded.

In view of the importance of sulphur metabolism it is certainly desirable that further work should be done on this problem.—I am, Sir, yours faithfully,

JOSEPH RACE,
Biochemist to the Devonshire Hospital.

Buxton, July 1st, 1927.

COLOUR TESTS FOR VITAMIN A.

To the Editor of THE LANCET.

SIR,—In an admirable paper under the above title in your issue of July 2nd Mr. S. G. Willimott and Mr. F. Wokes mention my observations on the destruction of vitamin A in cod-liver oil under the influence of sunlight and other sources of actinic rays, with the comment that no details were given of the period of exposure or of the distance from the mercury-vapour lamp. The omission of such data was not due to oversight on my part, but rather to the difficulty of expressing doses of artificial light in intelligible terms.

Since the question has been raised I may perhaps be allowed to draw attention to some points of importance in expressing dosage, and at the same time to supply the data which apply to the lamp I used in my experiments. In the absence of international units for comparing the output of arc lamps, simple statements of time and distance such as Messrs. Willimott and Wokes make in their paper, while they may be adequate for their own notes, give no accurate idea to other workers of the dose or range of light employed, since they refer only to two out of a number of variable factors. The following data apply to the destruction of vitamin A in a well-known brand of cod-liver oil under a Cowper Hewitt mercury-vapour lamp, taking a steady current from a bank of accumulators.

The oil is sealed in 10 cm. lengths of glass quill tubing of 7 mm. bore and 0·5 mm. wall thickness, one tube being filled as completely as possible. The glass of the tubes transmits the whole of the visible spectrum and the near U.V. to 3200 A.U. The tube is irradiated vertically beneath and parallel to the long axis of the mercury-vapour lamp, and at a distance of 10 cm. The exposure is started when the lamp has reached a steady output as registered by an ammeter in series and voltmeter in parallel with lamp. Control tubes of oil covered with black paper are kept: (1) at 10 cm. from the lamp; (2) at room temperature during the exposure.

Under the above conditions, with the lamp consuming 375 watts after an exposure of three-quarters of an hour, the oil gives a doubtful reaction and, after one hour, a definitely negative reaction with $AsCl_3$. Both control tubes show a strong positive reaction at the end of the exposure.

It would not be surprising if under similar conditions as regards power-consumption, time, and distance of exposure, &c., other lamps gave different results, but it would be interesting to know how such results compare with those of other laboratories. The observation of Messrs. Willimott and Wokes that the destruction of the vitamin continues after the oil has been removed from the source of light is important and is, as they say, a strong argument in favour of keeping the oil in the dark until the time of use.

The possibility of the production in cod-liver oil of some substance antagonistic to vitamin A is suggested by the above observation and is supported by some experiments I made last summer to test this point.

A series of dilutions of normal cod-liver oil in "deluminated" oil from the same source were made and tested at once with $AsCl_3$. A 20 per cent. dilution of normal oil gave a strong positive reaction, a 10 per cent. dilution was faintly positive, and a 5 per cent. dilution was negative. Twenty-four hours later the 20 per cent. dilution gave a reaction similar to the 10 per cent. freshly prepared dilution, but, after a further 24 hours, I failed to detect any further destruction of vitamin A.

Even a freshly prepared dilution of normal in deluminated oil did not give as good a reaction as the same dilution in an inert medium such as liquid paraffin. I am, Sir, yours faithfully,

Middlesex Hospital, W., July 12th. P. R. PEACOCK.

"TENNIS LEG."

To the Editor of THE LANCET.

SIR,—The treatment by massage and early movement, referred to in your annotation last week, was advocated and carried out by Wharton Hood. His little book entitled "Treatment of Injuries by Friction and Movement," which is, I believe, out of print, gave a clear account of the accident and its treatment. I have carried it out with absolute success for 20 years, the last case being a rather severe muscle-fibre tear in my own calf through jumping out of a dog-cart on to a very rough road. My practice is to rest the leg for 48 hours, then to lay overlapping strips of strapping from below the swelling and tender point to above its upper margin, and get the patient to walk, or rather hobble, about. There will be pain, of course, but this diminishes day by day if an honest attempt is made to walk and massage given over the strapping. As the strapping gets loose it should be replaced, and if well soaked with petrol will come away painlessly (and hairlessly). In my own case I was walking well but cautiously in a fortnight and was practically normal in three weeks after the injury.

I am, Sir, yours faithfully,

July 12th, 1927. G. P. JAMES.

QUININE AND CHINOSOL SUPPOSITORIES.

To the Editor of THE LANCET.

SIR,—In your issue of July 2nd the Medical Research Committee of the Society for Constructive Birth Control recommends a contraceptive suppository of chinosol. Chinosol has been widely used for this purpose for some years in Germany, England, and the United States, but the results, on the whole, have been even less satisfactory than those obtained with quinine. A considerable number of women are unable to tolerate chinosol in any medium, or in any concentration which is sufficient to act as a reliable contraceptive, and its use is frequently followed by inflammation and discharge. I have seen many such cases in my own practice, and many more were reported to me by German and American colleagues.

I saw a New York surgeon perform an artificial insemination (unhappily unsuccessful) on a doctor's wife who was suffering from cervicitis and sterility, which he attributed to the use of chinosol. She had been under his care for many years and he had attended her in her previous confinements. He was convinced that she had become sterile as a result of using a well-known chinosol jelly. He gives birth-control advice to his patients when they ask for it, so he cannot be suspected of any hostility to contraception in general. The medical officer of a large birth-control clinic in New York also told me that she had seen inflammation and discharge following the use of chinosol in a large number of cases.

There is a good deal of evidence accumulating that almost all the chemicals usually employed for contraceptive purposes tend to cause discharges and inflammation, and I believe that this is because they destroy, or at least weaken, Döderlein's bacillus, which is a normal inhabitant of the vagina, and which acts as a defensive army against the onslaughts of pathogenic organisms. Döderlein's bacillus, being a lactic-acid-producing bacillus, is unharmed by the presence of

lactic acid in a strength of 1 per cent., which is sufficient to kill spermatozoa if they are brought in contact with it.

Dr. W. Carey, visiting gynæcologist at Brooklyn Hospital, N.Y., and myself began, independently of one another, to use a lactic-acid jelly some six years ago and both of us have found it most efficient if used in conjunction with an occlusive pessary. In addition several hundred doctors to whom I have recommended it inform me that they have found it reliable and harmless. In my own practice I have advised its use to several thousand patients, and so far no harmful results have been reported to me. Five patients have complained that it caused a smarting sensation, and in all these cases I have found that there was *previously* a hyperæsthesia which had at times caused dyspareunia. In these cases I recommended chinosol or boracic instead of lactic acid. Apart from these five women, who complained of temporary discomfort, no harmful or even disagreeable results have been reported to me even by patients who have used it regularly for as much as five years.

I am, Sir, yours faithfully,

Harley-street, W., July 5th, 1927. NORMAN HAIRE.

NOMENCLATURE OF ENCEPHALITIS.

To the Editor of THE LANCET.

SIR,—May I ask for the hospitality of your columns to advocate a desirable change of nomenclature? At present it is usual to classify cases with symptoms of organic nervous disease following (or presumably following) acute encephalitis lethargica as cases of *post-encephalitis*, or *sequelæ of encephalitis*. These cases should be more correctly designated *chronic encephalitis* both on clinical and pathological grounds; and as from the beginning of this year, this nomenclature has been introduced into the register of cases at this hospital.

Clinically we know that the condition is usually a slowly progressive one, and a histological examination of the appropriate region post mortem always shows evidence of a recent active inflammatory process as opposed to simple healed lesions. The following clinical note is relevant:—

Yesterday a boy of 14 years was admitted into the hospital complaining of somnolence and pain in the right shoulder for one week. Prior to this he had always enjoyed perfect health and an exemplary character. During the last week his character has undergone a complete change. He has become moody and "difficult" and has been guilty of petty pilfering (such as stealing cherries from a shop-front) on three occasions. He is, I believe, suffering from acute encephalitis, in the modified form which is now becoming familiar, but at the same time he is showing from the onset a "characterological" change of the type which is usually called "post-encephalitic."

It is possible that there are cases which show undeniable evidence of the morbid process having undergone complete arrest, and such patients might appropriately be said to be suffering from the sequelæ of encephalitis, but the term should be reserved for these cases only. Incidentally there is a type of case which can be admirably designated *subacute* encephalitis lethargica (or epidemic encephalitis).

I am, Sir, yours faithfully,

E. B. STRAUSS,
Senior Medical Registrar, Hospital for Epilepsy and Paralysis.

Maida Vale, London, W., July 5th, 1927.

ILFORD EMERGENCY HOSPITAL.—Lady Patricia Ramsay has opened the war memorial children's wing of this hospital. It is hoped that the two acres of land surrounding the hospital will be utilised as a memorial garden available for special occasions.

THE LATE DR. F. K. RIDER.—Dr. Frederick Kirke Rider, of Leeds, who died on July 4th at the age of 62, was a well-known practitioner in East Leeds, and until his retirement from practice a few years ago was a member of the Leeds Panel Committee. A student at the medical school of Leeds, he qualified L.S.A. in 1892, later becoming L.M.S.S.A. He was a pioneer in both cycling and motoring in Leeds. He leaves a widow, two sons, and two daughters.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

A GROUP OF HEALTH RESORTS.

THE following are some of the statistics of six health resorts for 1926:—

Name of district and mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Diarrhœa under 2 years	Infant mortality.	Maternal mort. from childbirth.
Torquay .. .. (36,990)	13·7	14·4	1·40	1·73	2·2	2·9	4·0	63	6·0
Tunbridge Wells (34,430)	13·3	13·6	0·84	2·30	1·7	2·2	4·4	61	2·2
Ramsgate .. .. (30,270)	16·5	13·1	0·99	1·75	1·3	1·9	11·9	72	6·0
Margate .. .. (27,950)	14·4	11·0	0·86	1·36	0·8	1·6	7·4	45	7·4
Lytham St. Anne's (23,910)	10·9	13·7	0·83	2·13	1·2	1·9	11·4	57	15·0
Bognor .. .. (14,020)	12·0	9·3	0·43	1·42	1·2	1·8	0·0	41	0·0

In the above table the death-rates from causes such as cancer and heart disease are high because the aged and infirm go to live in health resorts for their climatic and other advantages. This does not apply so generally in the case of tuberculosis, owing to the use of sanatoriums. The environment which is good for the invalids should be productive of low infant mortality-rates and low maternal death-rates among the more permanent resident populations.

The hours of bright sunshine recorded in 1926 showed a considerable range. They were: Torquay, 1699; Ramsgate, 1681; Margate, 1653; Bognor, 1639; Tunbridge Wells, 1458; and Lytham St. Anne's, 1211.

Torquay.

Dr. Thomas Dunlop recounts the physical and climatic advantages of this borough, and mentions that the population more than doubles itself during the season. The up-to-date medical baths are claimed to be equal to anything at home or abroad. The sunshine (1699·5 hours in a poor year like 1926) and the possibility of open-air life make Torquay a good place for children. Dr. Dunlop says a better infant mortality record might be expected. The figures for the five years preceding 1926 were 81, 47, 49, 53, and 64. There is no antenatal clinic as yet, but 25 expectant mothers made 61 attendances by appointment at the school clinic. (The total number of births in the town was 507.) There is as yet no lying-in home for ordinary cases, but it is hoped to have such accommodation in the proposed new general hospital. Out of 1379 school-children examined only 27 per cent. were found to be adequately protected by vaccination. Of four cases of enteric fever notified one had an interesting history, the patient being apparently infected by living in the same house as a typhoid carrier who gave rise to an outbreak of a dozen cases in 1913.

The upland Dartmoor water, clarified by mechanical filters, has the advantage of being soft but not plumbo-solvent. Steps are being taken to prevent flooding in certain areas by increasing the sewerage facilities. Dr. Dunlop complains that the butchers do not coöperate in preventing the sale of diseased meat. By arrangement with the Newton Abbot R.D.S., the borough does the inspection of carcasses in the slaughter-houses just over the boundary. During the year 246 pigs' heads were condemned for tubercle, 61 of these being exposed for sale in shops. Dr. Dunlop would like to see a public abattoir

and a central depôt for meat inspection established. Designated milks show some progress. There is one producer of Certified milk in the borough and the council obtain Grade A (T.T.) milk for their refreshment rooms, for the open-air and secondary schools, and for necessitous mothers. There is big business in ice-cream during the summer months. The places of preparation were not always satisfactory, and one of them was a bedroom. Six samples of ice-cream were examined for *Bacillus coli*, each with a positive result, and, seeing that the ingredients are raised to the boiling-point, Dr. Dunlop blames dirty utensils for the contamination. During the year 369 houses were erected with State assistance, but of these only 31 municipal houses were available for renting, and therefore the relief to those most in need was trifling. On the Windmill Hill Council Estate 16 flats and 43 houses are to be erected. Dr. Dunlop puts in a plea for smaller flats and houses, but the policy of the Ministry of Health is to deal with the largest families first. There are several insanitary areas waiting to be sanified. For the "Pimlico" area, houses for the "to be dispossessed" have been erected and temporarily let to other tenants urgently needing them. If the dispossessed agree to take the houses erected for them, the temporary tenants will have to be moved into other council houses.

Tunbridge Wells.

Dr. F. C. Linton points out that the death-rate of 13·6 becomes a rate of 9·9 when corrected for the age and sex constitution of the population by the Registrar-General's factor. For about one-half of the year the water from springs in the Tunbridge Wells sandstone meets requirements. During the remainder of the year the spring water is supplemented by seven artesian wells at Pembury, whence it is pumped to a distributing reservoir 500 ft. above sea-level. The borings of the artesian wells pierce the Wadhurst clay and bring water from the underlying Ashdown sands. This water contains some iron which is effectively removed by Candy oxidising pressure filters, and there is also about an acre of open filter beds. The Ashdown sands reach the surface some miles from the bore wells. The temporary and permanent hardness are given as 3·5. Until the dry season of 1921 the sources mentioned were thought to be sufficient for the population, but it is now regarded as advisable to increase the supply, and, after an inquiry by the Ministry, it has been decided to tap the Ashdown sands to the north-west of the borough by a fresh bore-well about seven miles distant from the existing artesian wells. The method of refuse disposal has also been under review and it has been decided to study the plan adopted in Bradford, which it is hoped will prove less costly than treatment by a destructor.

A fund is being collected to meet the cost of transferring the general hospital from its cramped and noisy position to a more open and quieter site on the Mount Ephraim ridge. There is no municipal maternity home, but the corporation made an agreement in April, 1926, with a "voluntary" home for the admission of necessitous cases where the home environment is unsuitable. The dental practitioners have combined to form a district public dental service for the benefit of persons who are unable to pay large fees.

Ramsgate.

Dr. W. J. Bannister reports that the number of houses built during the year was much larger than in any year since the war, and with the completion of a considerable number of the houses of the council's scheme the prospect of substantial relief during 1927 is brighter. During the current year it should be possible to make progress with the Ratcliffe Square unhealthy area and to demolish some of the most unsatisfactory dwellings in the district. The death-rate of 13·1 becomes 10·9 when corrected for age and sex constitution of the population. Ramsgate compares unfavourably with other places as regards the number of uncertified deaths. The percentage for 1926 was 3·96, as compared with 1·0 for England and Wales, 0·5 for the 105 large towns, and 1·1 for the 158 smaller towns. The routine medical inspection showed that about 40 per cent. of the school-children are vaccinated. Antenatal clinics are conducted once a fortnight by a local medical practitioner. The shell-fish from Pegwell Bay are not allowed to be sold for human consumption until they have been sterilised for six minutes by steam under pressure. The council provides and works a sterilisation station at Broad-street, and no charge is made to vendors of shell-fish for use of the station. The water-supply is a hard chalk water and contains over 24 parts per 100,000 of chlorine as "salt." The adits from which the water is pumped are over one mile from the sea. The sewage is got rid of by gravitation without pumping and is conveyed through the outfall sewer to a point over 1250 ft. from the shore, whence it is carried by currents straight out to sea, whatever the state of the tide. An unusual nuisance caused by the rotting carcass of a whale about 24 ft. in length and weighing three tons had to be removed by the sanitary inspector from the foreshore. The control of the ice-cream trade is difficult as there is no power to compel the registration of ice-cream vendors, who suddenly increase in numbers during spells of hot weather.

Margate.

Dr. Rowan McCombe says that the population during the height of the season exceeds 100,000. A scheme is in hand for the erection of a much larger hospital in lieu of the existing cottage hospital. It is badly needed. There are four midwives practising in the town. Two are municipal, and at very little cost to the ratepayers confer incalculable benefits on poor people. They occupy their spare time in antenatal visiting.

The Margate Corporation supply water to 21 outside parishes. The water is pumped from deep wells with connecting tunnels in the chalk. An analysis gives the hardness as 18·2 before boiling and 3·8 after boiling, and the amount of chlorine expressed as "salt" as 3·69 gr. per gallon. The whole of the sewage has to be pumped twice a day for about one hour at high tide and is discharged at deep water about 600 yards from the cliff, having previously undergone a screening process. The housing problem is aggravated by the workers who come into the town every season to cater for visitors and remain in the town after the season is over, and in spite of the efforts of the corporation there are still a large number of families requiring houses. From 1921 to 1925 the corporation erected 206 houses and at present 150 are being built on the Dane Valley Estate, 24 of these having been completed during 1926. Great difficulty is being experienced in inducing ratepayers to use proper bins for house refuse and to keep them in a sanitary state. Action is to be taken under the local Act of 1926 to bring about a better state of things. An outbreak of paratyphoid occurred in a children's institution during the year; it was attributed to infected meat. There were 111 cases, mostly of a mild character and there were no deaths.

Lytham St. Anne's.

Dr. John P. Litt informs us that his borough is a seaside resort with a coast-line of 6¾ miles, facing successively south, south-west, and west, and extending from the estuary of the Ribble to the southern boundary of Blackpool. The population is more residential than industrial, though there is a slipper works, an aircraft works, a shipbuilding and engineering works, and several laundries. None of these has any specially bad influence on health. The infant mortality has come down to its present figure (57) from 143 in the last quinquennium of the nineteenth century, and 114 in the first quinquennium of the present century. The water is soft and derived from the impounding of the rivers Calder and Hodder and the Grizedale Brook. The sewage from the Lytham district is pumped into settling tanks and discharged into the sea one hour

after high tide. The works of re-sewering a large portion of the area is now in progress. The Ribble mussel beds were closed during 1926 and the borough treasurer and medical officer have been instructed to report on the mussel purification tanks at Conway. The condition of a portion of the cockle beds is under investigation. During the summer months a number of boys' brigades, cadet corps, and boy scouts camp in the open fields of the borough, and arrangements are made to ensure adequate water-supply and accommodation. The general standard of housing is very good and there are no back-to-back houses or unhealthy areas. The number of houses erected during the year was 254, including 56 municipal houses and 48 others erected with State assistance. There are 80 more municipal houses in course of erection. There are two public slaughter-houses, one at Lytham and the other at St. Anne's, and no private slaughter-houses. The veterinary inspector reports that he examined the milch cows, numbering about 560, every quarter. Twenty-one cases of suspected tuberculosis were reported to the county council, and of these 20 were considered to be infected and were slaughtered. The diagnosis was confirmed in each case; in one the larynx was chiefly affected, and in two the udder, whilst the remainder were cases of tuberculosis of the lungs or tuberculous emaciation. The standard of cleanliness was better than in previous years, grooming of cattle being more general. Proceedings were taken for milk below the standard in two cases; one was 16 per cent. deficient in fat and the other indicated a 9 per cent. addition of water. Both cases were dismissed at the Lytham police-court. All the elementary schools are supplied with formalin sprays. An up-to-date maternity block has been added to the St. Anne's war memorial hospital by the generosity of a local lady. The block was opened on Nov. 9th, and contains one four-bed and two single-bed wards, a labour room and an observation ward. The fee fixed is £3 3s. per week and the local authority intends to contribute a portion of the fee when necessary. It is hoped that the borough will take part in the county orthopædic scheme in respect of both ex-babies and school-children. At present specialist advice is obtained for urgent cases, but owing to the want of following-up little benefit results.

Bognor.

Dr. T. Philips Cole reports that his district is supplied with hard water from deep wells at Eastergate, about 4½ miles north of the town. Sewage is dealt with by two large storage tanks and a pumping station. The outfall is closed from five hours after until one hour before high water, during which time the sewage is pumped from the low level tank to the high level. New streets are now laid with surface water sewers, but the bulk of the storm-water at present passes into the foul water sewers and throws too great a strain on their capacity. It will be necessary shortly to make special provision for surface-water. Progress has been made in the erection of small houses during the year. The council built 41—12 parlour and 29 non-parlour. A firm of builders erected 34 parlour-houses to be let at a weekly rental. A further 51 have been built by private individuals with State assistance and the council have continued their policy of advancing loans up to 90 per cent. of the value of the houses. The waiting-list still contains the names of 127 residents. There were 41 milk samples examined for tubercle. Three which gave a positive result were all taken from one retailer, who had a mixed supply of milk from herds outside the district. The matter was reported to the county council. The herds were examined and one cow slaughtered. Further samples, however, were still positive and the matter was again reported to the county council and was still under investigation at the end of the year. Bacterial examinations of 66 samples were made to investigate cleanliness; 47 per cent. had under 30,000 bacteria (Certified standard); 81 per cent. had under 100,000; 97 per cent. had under 200,000 (Grade A standard); and 73 per cent. showed *B. coli* absent. These figure show an advance on the 1925 results. The bacteri examination of ice-creams gave very uneven result the bacteria per c.cm. varying from 1000 to 286,00 As the result of repeated testing and effort on the pa of the maker one lot of ice-cream improved fro 86,000 bacteria at the first test to 1000 at the seventh Diphtheria and scarlet fever have shown a sligh prevalence only during the past five years, an Dr. Cole attributes this to the fact that most of th susceptible individuals were attacked during th epidemic years 1919 to 1921.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 2ND, 1927.

Notifications.—The following cases of infectiou disease were notified during the week:—Small-po 228 (last week 259); scarlet fever, 1534; diphtheri 735; enteric fever, 89; pneumonia, 800; puerper fever, 41; puerperal pyrexia, 96; cerebro-spina fever, 9; acute poliomyelitis, 6; encephaliti lethargica, 38; dysentery, 10; ophthalmia neona torum, 117. There were no cases of cholera, plague or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, includin London, there was 1 death from small-pox (belongin to Oldham C.B.), none from enteric fever, 27 (1) fro measles, 6 (3) from scarlet fever, 20 (8) from whooping cough, 16 (3) from diphtheria, 36 (8) from diarrhœ and enteritis under two years, and 28 (3) from influenza The figures in parentheses are those for Londo itself.

Obituary.

LEWIS DAVIE CRUICKSHANK, M.D. ABERD., M.R.C.P. EDIN., D.P.H.

WE have to record the death, on July 10th, Dr. L. D. Cruickshank, following an attack of influenz The medical staff of the Scottish Board of Healt loses a valuable member, whose gifts were used t advantage in the public service.

Lewis Cruickshank was born at Tarves, Aberdee shire, in 1875. At the age of 17 he was alread manager of a wholesale drug business in Aberdee and when in 1902 he graduated in medicine at th University he was awarded the John Murray Med and Scholarship, and was regarded as the mo brilliant student of his year. After a short tim spent in pharmacological research and privat practice, he became medical officer and lecturer t the Aberdeen Provincial Training College, where was his duty to instruct school-teachers in the pri ciples of hygiene. From this work he passed on t the post of principal of the College of Hygiene an Physical Training at Dunfermline, in which capacit he visited Denmark more than once in order t familiarise himself with modern methods. Th reorganisation effected at the College led to i becoming a central institution under the Scottis Education Department, and Dr. Cruickshank's succe was recognised by his being made the first full-tim medical officer and chief inspector of physical trainin to the Department. Here it was his duty to supe intend the physical education given in more tha 3000 State-aided schools; he had control of numero assistants in this work, and as he was also responsib for the medical examination of school-children, an for the care of the feeble-minded, he acquire exceptional experience of public health work in i relation to education. This experience was frequent utilised on behalf of the Society of School Medic Officers, in the affairs of which he took a promine part. In 1919 the care of school-children ca under the ægis of the Scottish Board of Health, a Dr. Cruickshank was transferred to the Boar staff, as a member of which he was given charge important inquiries covering a wide field. Th

work gave him plenty of scope for using his powers as an organiser and for applying his notable constructive ability. The last investigation on which he was engaged was the special inquiry made to determine the nutritive value of milk as a food for growing children. This inquiry, conducted in conjunction with Dr. J. B. Orr, director of the Rowett Institute, is said to be the largest of its kind ever made in Scotland, and it is hoped that the results to be published will be of great value.

Dr. Cruickshank leaves a widow and three sons.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

MENTAL DEFICIENCY BILL.

THE Mental Deficiency Bill was considered by Standing Committee A of the House of Commons on June 28th. Sir RICHARD BARNETT was in the chair.

Clause 1 (definition of defectives) reads as follows :—

(1) The following Section shall be substituted for Section 1 of the Mental Deficiency Act, 1913 (in this Act referred to as "the principal Act")—"1.—(1) The following classes of persons who are mentally defective shall be deemed to be defectives within the meaning of this Act: (*a*) Idiots, that is to say, persons in whose case there exists mental defectiveness of such a degree that they are unable to guard themselves against common physical dangers. (*b*) Imbeciles, that is to say, persons in whose case there exists mental defectiveness which, though not amounting to idiocy, is yet so pronounced that they are incapable of managing themselves or their affairs, or, in the case of children, of being taught to do so. (*c*) Feeble-minded persons, that is to say, persons in whose case there exists mental defectiveness which, though not amounting to imbecility, is yet so pronounced that they require care, supervision and control for their own protection or for the protection of others, or in the case of children, that they appear to be permanently incapable by reason of such defectiveness of receiving proper benefit from the instruction in ordinary schools. (*d*) Moral defectives, that is to say, persons in whose case there exists mental defectiveness coupled with vicious or criminal propensities, and who require care, supervision and control for their own protection or for the protection of others. (2) For the purposes of this Section 'mental defectiveness' means a condition of arrested or incomplete development of mind existing before the age of eighteen years, whether arising from inherent causes or induced by disease or injury."

Colonel WEDGWOOD moved in substituted Subsection (1) (*c*) to leave out the words "for their own protection or." He said that while there was not much difference between paragraphs (*a*), (*b*), and (*c*) and the wording of the original Acts, these particular words were novel. He preferred the definition in the original Act. It has been stated on the second reading of the Bill that it was intended primarily to deal with the victims of encephalitis lethargica; persons who developed feeble-mindedness after the period of infancy. With that proposition he had no complaint at all. There did not seem to be any difference between feeble-mindedness developed in infancy and feeble-mindedness developed later on; the same law should apply, but there was a considerable alteration in the definition of moral defectives in paragraph (*d*). The real danger of the Bill was that they brought within its scope a large new class of people who would be liable to be sentenced for life to these homes for mental defectives. Did they really want to get in the definition of feeble-minded, immoral girls who walked the streets, and who were feeble-minded to a certain extent as far as their moral capabilities could be measured, but were otherwise not feeble-minded at all. The chief argument was that such women bred unrestrained feeble-minded children. He did not think that was proved, but medical men knew better than he did. These girls were quite as fully acquainted with all the modern devices for preventing propagation as any other section of the community, and he did not think they bred more than others. If they did, he did not believe in the interests of the community that they ought to stretch the definition of feeble-mindedness to include them. These words, "for their own protection," were the dangerous words. As long as feeble-minded people were dangerous to others they came under the same law as lunatics, and they must be shut up. But these words "for their own protection" took in people who were not a danger to the community; people who were merely immoral and who, well-intentioned people thought, should be protected for their own sake. If they could protect them and leave them free by all means let them do so, but if they could only protect them by putting them away for life, then in considering what form of protection they ought to apply, they should compare it with the desirability of leaving people who were not a danger to the public to carry on an immoral life.

Mr. CROMPTON WOOD said that he did not think under the Mental Deficiency Act there was any imprisonment for life. The tendency was to try to get rid of these patients as quickly as possible. There was nothing like enough room for all the patients who wanted attention, and certainly the precautions taken and the continual examination of these people quite precluded any suggestion that they were imprisoned for life. If the Committee left out these words they barred from institutional care all those who were not a menace to other people, but who still wanted care, supervision, and control. They wanted to bring under this Bill as many people as needed its benefits. The people who would be excluded if these words were omitted needed the benefits such as care, teaching, and nursing, and what was much more important, the most skilled medical advice which they could never obtain in their own homes. Colonel Wedgwood was asking the Committee to legislate in one way for the rich and another way for the poor. It was estimated that about 10 per cent. of the young people who went through these great institutions were enabled to go out into the world largely owing to the care and attention which they received. This amendment would ruin the whole meaning of the Mental Deficiency Acts.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that from the point of view of his department he could not advise the Committee to accept the amendment. Colonel Wedgwood's remark about locking these people up for life was a complete misstatement of the position in regard to the treatment which people got in these institutions to-day. He should have thought that nothing would have appealed more to the humane feelings of anyone than that steps should be taken to give these people such assistance as was possible in these institutions. To confine the clause to those who could only be sent to these institutions for the protection of others was an impossible course of action which he did not think anyone would care to adopt. With regard to the question how this clause would come into operation, the answer was that it would come into operation in the way laid down in the ordinary law. If anyone was considered to be a subject for the operation of the clause there would have to be two medical certificates, and the matter would have to be dealt with by the justices of the peace. When a person was put into an institution in that way it was always subject to the opinion of the Board of Control, and there was ample opportunity for revision. Full opportunity was given for patients to be discharged if they were cured or able to be discharged.

Mr. RHYS DAVIES said he knew a case where five children were feeble-minded. None of them had ever been taken away from home until one was found after a football match wandering in the streets and not able to find his way home. He was taken to an institution and remained there. He (Mr. Davies) thought that the other four would be better in an institution; but the parents were all right mentally, and they thought that the children were better under their care. If the Committee passed this clause, would it then be possible for the authorities to come into the home of these people and take their four children away from them without those four children committing any offence at all? He had a little fear on that score.

Sir K. WOOD: I do not look at the matter in that way. We must not wait until an offence is committed. The whole operation of this law and the present administration is to prevent offences being committed. We do not want to wait until unhappily one of these four children commits some of those offences of which we read in the newspapers.

Mr. DAVIES: Then you could put the whole community into an institution in that case?

Sir K. WOOD: No. The hon. Member overlooks the many provisions for the supervision and release of people of this kind. We do not want to break up families and remove children from their parents unless it is for the benefit of the children themselves. That is the idea which animates the administration of this Act, and therefore we could not possibly accept the amendment.

Mr. CHARLETON said he had a mentally defective boy who was even worse than the category under discussion. He knew scores of working-class families in the same position, and this clause would cause a great deal of trouble and anxiety to those people. He thought that it would be better if some safeguard were inserted in the clause.

Sir K. WOOD said that he was afraid he had not made the matter clear. The Mental Deficiency Act, 1913, provided that where the parent or guardian was not asking for the child to receive this care—

"the order shall not be made without the consent in writing of the parent or guardian unless it is proved to the satisfaction of the judicial authority that such consent is unreasonably withheld or that the parent or guardian cannot be found, but consent shall not be deemed to be unreasonably withheld, if withheld with *bona fide* intention of benefiting the defective."

The amendment was negatived.

Mr. CHARLETON moved in the substituted Subsection 1(*d*) to leave out the words "Moral defectives, that is to say."

He said he moved this formally in order to get some explanation of the meaning of these words.

Mr. RHYS DAVIES said that the persons to whom this Bill referred were divided into four categories—idiots, imbeciles, persons mentally defective, and cases of moral defectiveness. He was not arguing against these words, but they ought to have a clear understanding of the exact position. There was a feeling that this Bill introduced something new by declaring moral defectives as falling within the category of the cases provided for under the Act of 1913. He knew a case of a boy of 15 who committed an offence against a little girl 6 years of age. That case was brought before a court, and instead of the boy being sent to a reformatory school he was found to be mentally deficient and he had been shifted several times from one institution to another. He had been in communication with the medical officers of the institutions where the boy had been sent, and his opinion was that if the boy was not going to be in an institution for life he would be there for a very long time. It was rather terrible to contemplate the possibility of that boy being detained for five or ten years for a single offence of this kind. If he could get an explanation of the type of case to be dealt with under this paragraph he would be satisfied.

Sir K. WOOD said this amendment, taken together with another which stood on the amendment paper, would have the effect of confining paragraph (*d*) of Subsection (1) to encephalitis lethargica. Unfortunately a very large number of people suffered from a good many other things of an abnormal type. These people committed all sorts of unnatural offences which must be dealt with not only in their own interests, but in the interests of the community as a whole. It was not the offence which had to be considered, but whether in the person who was affected there existed mental defectiveness coupled with vicious or criminal propensities.

The amendment was withdrawn.

Clause 6 (which amends Sections 21 and 30 of the principal Act) reads as follows :—

(1) Section 21 of the principal Act (which relates to the central authority) shall have effect as if after the word "supervision" there were inserted the words "training" "occupation." (2) Section 30 of the principal Act (which relates to the general powers and duties of local authorities) shall have effect as though—(i) after paragraph (*c*) thereof there were inserted the following paragraph : (*cc*) to provide suitable training or occupation for defectives who are under supervision or guardianship or have been sent to certified institutions. (ii) in proviso (i) thereto there were substituted for the words "paragraphs (*b*), (*c*), (*d*), and (*g*)," the words "paragraphs (*b*), (*c*), (*cc*), (*d*), and (*g*) ; (iii) at the end thereof there were added the following proviso : (v) a local authority shall be under no obligation to provide training in the case of any defective under supervision if they satisfy the Board that there are in his case adequate reasons for not so doing.

Mr. CROMPTON WOOD moved in Subsection (2, iii, v), after the word "training" to insert the words "or occupation." Clause 6, he said, was one of the most important clauses in the Bill. The local authorities were responsible for the training and occupation of mental defectives after the age of 16, when they had left special schools. It was greatly in the interests of the poor part of the population that this training should be the duty of the community. When this matter was discussed with the county councils they agreed to accept this responsibility conditionally upon the insertion of Clause 5 (amendment of Section 11 of the principal Act), which was a rider to protect them from the obligation of providing training in the case of defectives under supervision if they satisfied the Board that there were adequate reasons for not doing so. They ought to have put in the rider the words "training or occupation." They had to consider cases occurring in country places where the defectives were far away from a place where training or occupation could be provided, and they must protect the county councils in cases of this sort. Those councils were accepting a great responsibility, and they must assist them by putting in these words.

The amendment was agreed to.

Sir K. WOOD moved the following new clause :—

If in any case in which, under Section 8 of the principal Act, a Court has directed a petition to be presented against any person and ordered that person to be detained pending the presentation of the petition and the adjudication thereof, it is found impracticable to present a petition or the petition is dismissed, then, unless the Court has otherwise ordered, that person shall, until he can again be brought before the Court, be dealt with as follows (that is to say) : (*a*) If the place in which he is being detained under the order of the Court is a prison or a place of detention provided under Section 108 of the Children Act, 1908, he shall continue to be detained in that prison or place. (*b*) If the place in which he is being so detained is not a prison or such a place of detention as aforesaid, he shall be removed therefrom to a prison or, if he is a child or young person, to a place of detention, or if in the opinion of the Secretary of State it is inexpedient that he should be removed to a place of detention, then to such other place as the Secretary of State may by order direct.

He said that the difficulty was caused through a curious oversight in the drafting of the principal Act of 1913. Under Section 8 of that Act in certain circumstances a court of justice might postpone the passing of sentence on a defendant brought before it and direct that a petition should be presented to a judicial authority with a view to obtaining an order that the person should be sent to an institution for mental defectives or placed under guardianship and the court was empowered to order that the person be detained in such institution or place of safety for such time as was required. That was all very satisfactory and right and the provision had worked smoothly, but the Home Office had had a number of cases where apparently no provision was made under the law, and where as a result of further observation and examination of the person the local authority had been unable to present the petition and send the person to an institution on the ground that the medical men agreed that it was not a case of defective mentality but a case of the person being a criminal who ought to be dealt with by the Court which originally suggested that the petition should be presented. It was a curious thing that in that case apparently there was no provision at the present moment to detain that person and bring him back to the original court again. Paragraph (*a*) was provided with a view to making sure that in such a case such a person should not go free. Paragraph (*b*) was moved with the object of bringing the clause into line with the other provisions of the Children Act, which governed the placing of children in places of detention.

The clause was read a second time and added to the Bill.

Sir K. WOOD moved the following new clause :—

Every joint committee or joint board constituted under Section 29 of the principal Act shall be a body corporate by such name as the order constituting the committee (whether the order was made before or after the passing of this Act) may direct, and shall have perpetual succession and a common seal and may hold land for the purpose of their powers and duties without licence in mortmain.

He explained that this clause was moved with the object of removing doubts and regularising the position of certain joint bodies who had been incorporated under Section 29 of the principal Act which empowered the Minister to make an order where two or more local authorities desired to join together in this way. It had been questioned whether the present law was sufficient for them to do so. Already five local authorities had found it convenient to administer the Act in this way, and at the present moment they had two further applications in that connexion.

The clause was read a second time and added to the Bill.

Mr. ELLIS moved the following new clause :—

"Section 44 of the principal Act (which relates to the determination of residence) shall be amended by the insertion therein after Subsection (2) of the following new Subsection :—(2*a*) Where the order is made by a judicial authority and is in respect of a person in an institution for lunatics, certified institution, approved home, or other public or charitable institution, that person shall for the purposes of the provisions of the last foregoing section be deemed to have resided in the place which was his place of residence immediately before he was received into the institution or home, and if for the purpose of or in connexion with his reception into the institution or home any place was determined to have been his place of residence, that determination shall be conclusive."

He said that the object of the clause was to settle financial responsibility as between two authorities. Under the old Act a very curious position was found to arise. In his constituency of Wakefield there was situated partly on the border and partly inside his constituency the asylum of the West Riding Authority. That asylum in consequence of the necessity of dealing with certain cases which were deemed to be mental deficients rather than lunatics had removed several of their patients to their residences. The place of residence appeared to be actually within the borough of Wakefield, and the effect had been to cast the financial responsibility for West Riding patients on to the borough. This clause was intended to make it clear what the place of residence was and to ensure that in the future mental deficients belonging to a particular place should be paid for by that place.

Sir K. WOOD said that he thought the case which had been raised by the hon. Member was one that ought to be dealt with, and he had therefore much pleasure in accepting the new clause.

Lieut.-Colonel FREMANTLE said that he had been asked to move an amendment to the clause on behalf of the London County Council. It was to insert at the end the words—

"Provided that for the purposes of this Subsection the place of residence shall be deemed to be (1) in the area of the County or County Borough in England and Wales."

Sir K. WOOD said that he would suggest that his hon. friend consulted with him later and that the matter should be dealt with on the report stage.

Lieut.-Colonel FREMANTLE said that he was quite prepared to do that.

The clause was read a second time and added to the Bill.

The Committee stage was concluded and the Bill, as amended, was ordered to be reported to the House.

HOUSE OF LORDS.

THURSDAY, JULY 7TH.

LIQUOR (POPULAR CONTROL) BILL.

THE debate was resumed on the second reading of the Liquor (Popular Control) Bill.

The Earl of DUNMORE said that the effect of the expenditure every year of £300,000,000 of our national wealth on intoxicating liquors, especially at a time when most of our industries were struggling with high taxation and other adverse circumstances, was very difficult to estimate. Its effect was probably to be seen in some of the most pressing political problems of the day. It certainly made the argument of some of their lordships, including Lord Dawson that this social evil of drink was a disappearing factor in our national life, seem to be hardly justified by facts. He thought that the Bishop of Liverpool came much nearer to the truth when he told the House that sooner or later the country would have to tackle this question, and that the only road to a solution of the problem lay in taking the trade out of private hands. He believed that this Bill gave a liberty for experiment to a large section of the electorate which was badly needed.

Earl RUSSELL said that at an earlier part of the debate they had one of those very interesting speeches which they got too seldom from Lord Dawson. As he had done on previous occasions, the noble lord had given a certain amount—he might almost say a considerable amount—of praise to the advantages of alcohol in civilised society, and he finished off in an almost lyrical passage by saying that it added to, and was to a large extent the cause of, the frolic and fun of the world. When he listened to those words he (Earl Russell) wondered for a moment whether their lordships had here a reincarnation of the Persian tentmaker, or perhaps of Dionysius, not at all the sort of figure which one would have normally associated with Lord Dawson. He was rather interested also to notice that later in his speech, when Lord Dawson came to deal with young soldiers at Aldershot, who went to the dry canteen and did not take liquor, he repeated, apparently with approval, what had been said to him by a general or a colonel to the effect that they were fine upstanding young men, and one could see at once by their faces that they did not take drink. These two propositions did not seem to him (Earl Russell) to be quite consistent. When one contemplated the enormous harm that was done in this country by the consumption of drink—the poverty which it entailed, the misery to which it so often gave rise, and the injury, small in many cases, no doubt, but constant, to the general health of the population, injury to which Lord Dawson bore unwitting tribute when he referred to those fine upstanding young men—it seemed to him very much to be regretted that such important leaders as a distinguished doctor and a right reverend Prelate (the Bishop of Durham) should use words which would be quoted outside without their context, and would give rise to the impression that people who were the guardians, the one of the public health, and the other of public morals, did not think that there was anything to be said against the consumption of alcohol. When they were considering this subject it was not enough to say that this or that remedy had not been sufficiently considered, or that it was financially unsound. If the majority of their lordships were really convinced that some legislative move in the direction of temperance was desirable, in addition to the educative move, then they must not merely submit a negative to Bills of this kind, but they had a duty to support or suggest some form of constructive proposal. It was for that reason that when they came to the division he would vote for the principle of some legislative action being taken, and for some consideration being given to this Bill and its details in Committee. The question of total prohibition, even in an area, was, he admitted, a very difficult one. He confessed that he did not like the principle of a compelled morality in any form, but if a sufficient majority in an area thought that prohibition was desirable it seemed to him that the experiment might be tried. He agreed that there had been an immense improvement in the sobriety, self-restraint, and self-control of the people, and he believed that it was still going on. Although it was doubtful whether they would accelerate it by total prohibition, still he felt that at least they need not retard it by the present system of flaunting opportunities of drink and pressing people to drink not only more than was good for them, but more than they wanted.

The Earl of BIRKENHEAD (Secretary of State for India) said that as he listened to Earl Russell he was confirmed in his view that the Government were right in their conclusion that they were unable to support the Bill. The Bill had been riddled on its financial side, as well as on its theological, moral, and sociological side. It was framed on a principle which must fail because it was anti-social. It was claimed that the Bill was democratic, but a more amazing pretension was never put forward. Its proposals were ill-conceived, confusedly thought out, financially unsound, and in absolute antagonism to the spirit and traditions of the British people. That spirit and those traditions had throughout the ages, and not unsuccessfully, proceeded on the basis that a great confidence might be reposed in the moderation and commonsense of the humble folk of this country, and that moral improvement was to be imposed on them not by coercion and not by sermons, but by trusting them and making them the judges and trustees of their own morality, and treating them as the responsible custodians of their own moral forces.

Lord BALFOUR OF BURLEIGH regretted that the Government had thought fit to put on the Whips against this measure. He would vote for the second reading of the Bill, and he hoped that a sufficient number of the supporters of the Government would go with him into the lobby to show the Government that there was a strong feeling in the party in favour of constructive proposals for temperance reform.

On a division the motion for the second reading was negatived by 144 votes to 36—majority against, 108.

TUESDAY, JULY 12TH.

Medical and Dentists Acts Amendment Bill.

Lord LOVAT introduced the Medical and Dentists Acts (Amendment) Bill, which was read a first time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 6TH.

Hydroquinone and Lactic Acid.

Mr. FENBY asked the President of the Board of Trade if he was aware that the exemption orders applied for last year under Section 10 (5) of the Finance Act, 1926, in respect of hydroquinone and lactic acid B.P., being products liable to duty under Part I. of the Safeguarding of Industries Act, 1921, had not yet been issued; that his department were refusing to issue these exemption orders although the products in question were still not made in His Majesty's Dominions and that, in consequence, hospitals and other consumers of these products which had to be imported were compelled to pay at least one-third more than would otherwise be the case; and would he take steps to issue the exemption orders in question forthwith.—Sir P. CUNLIFFE-LISTER replied: An exemption order regarding hydroquinone was issued by the Treasury on June 23rd. Preparations for the manufacture in this country of B.P. lactic acid are well advanced, and the conditions for exemption laid down in Section 10 (5) of the Finance Act, 1926, are not therefore satisfied.

Post-vaccinal Encephalitis and Nervous Disease.

Mr. DAY asked the Minister of Health whether he would publish the full reports of the committee of inquiry which inquired into post-vaccinal encephalitis appointed by his department at the end of 1924.—Sir KINGSLEY WOOD replied: I assume that the hon. Member is referring to the committee appointed by one of my right hon. friend's predecessors in 1923. The terms of reference of that committee were limited to the consideration of the question whether any further experimental research could be initiated to throw light on the possibilities of vaccine lymph producing nervous diseases as a complication of vaccinia. The committee recommended that further research was desirable, and their report was referred to, and is under the consideration of, the Committee on Vaccination, which is now sitting. In these circumstances, my right hon. friend does not propose to consider the question of publishing the report of the committee appointed in 1923 until he has received a report from the present committee.

Mr. DAY: Is the hon. gentleman aware that this is referred to rather extensively on the Continent, and if that be so, does he not think it would be better to publish a report in this country?

Sir KINGSLEY WOOD: I think the hon. Member had better wait and see what the subcommittee do.

Food Adulteration.

Mr. DAY asked the Minister of Health the number of prosecutions instituted by his department, or by the inspectors under his control, for the adulteration of food for the 12 months ended to the last convenient date.—Mr. CHAMBERLAIN replied: Prosecutions in respect of the adulteration of food are not instituted by my department, but by local authorities and their officers. I am not in a position to state the total number of prosecutions undertaken in any period, but the reports which are sent to my department show that the number of samples of food taken in England and Wales during the 12 months ending on Dec. 31st, 1926, was 120,617, and that 7044 of these (or 5·8 per cent.) were found to be adulterated.

Dogs and the Public Health.

Sir G. COURTHOPE asked the Minister of Health whether his attention had been called to the increase in the number of dogs in urban areas and the consequent fouling of pavements and other public places; and whether he contemplated taking steps to reduce the number of dogs kept in towns in the interests of cleanliness and the public health.—Sir W. JOYNSON-HICKS (Home Secretary) replied: Yes, Sir. My attention was recently drawn to the increase in the number of dogs in London, and many local authorities have complained of the fouling of pavements. But any proposal to reduce the number of dogs would require legislation, and I am not sure that this would be supported by public opinion.

International Opium Convention.

Mr. CAMPBELL asked the Home Secretary which of the signatory Powers to the International Opium Convention of February, 1925, had deposited ratifications of that Convention; whether that Convention was now in force; and, if not, when it was likely to become operative.—Sir GEORGE HENNESSY replied: I understand that since the replies given to the hon. Member on Feb. 14th and Nov. 17th last, the Netherlands, Bulgaria, Czecho-Slovakia, and Poland have ratified the Convention. As stated in the reply of Nov. 17th, the Convention cannot come into force until the requisite number of ratifications prescribed in Article 36 have been deposited. H.M. Government have done their best to urge ratification by the other signatories.

Discovery of Girl's Body in Scotland.

Mr. SCRYMGEOUR asked the Secretary of State for Scotland whether he had completed his inquiries into the case of a girl reported to have been drowned, whose body was found at Invergowrie on June 12th; why the body was conveyed to the grave on a common lorry covered by sacking or tarpaulin, having been left till burial in an old shed; whether the cause of death was ascertained by a post-mortem examination; whether there was any evidence suggesting that the girl was under the influence of drink or drugged; why a photograph was not taken; and whether the police description gave details about the condition of her teeth, whether artificial or natural, and the value of her rings, if any.—Sir JOHN GILMOUR replied: I have obtained information on the points raised in the questions. I am informed that the body of the woman concerned was found on June 12th on the foreshore at Invergowrie, and was removed by the police to an unoccupied lockfast shed and examined by a doctor, who certified that death was due to drowning. The shed, according to my information, was suitable for the purposes of safety and decency, and also for purposes of identification. A description of the body and clothing was given by the police to the press and appeared in the newspapers. I am informed that the description did not give details about the teeth, which were natural and in good condition, but that it did refer to a ring worn by the deceased. A number of persons viewed the body but failed to identify it. The case was reported by the police to the Procurator-Fiscal, who reached the opinion that the case was one of suicide, and that there was nothing suspicious about it. A post-mortem examination in the form of dissection was not considered necessary. There was no evidence suggesting that the woman was under the influence of drink or had been drugged. A photograph was not taken because, in the opinion of the police, such a photograph would have been of no use for identification purposes in this case. After the Procurator-Fiscal was satisfied that there were no suspicious circumstances, the body was handed over to the sanitary authorities and buried on June 16th with the authority of a direction by a justice of the peace in accordance with Section 69, Subsection (1) of the Public Health (Scotland) Act, 1897. I am informed that the body was conveyed to the grave in a plain black coffin, carried on a lorry, and covered with an ordinary van cover. I see no reason for holding that proper steps were not taken in this case, but I think that the general question of taking a photograph for purposes of subsequent identification merits further consideration, and I propose to examine that question further in consultation with the Lord Advocate.

Insanitary Houses in Glasgow.

Mr. STEPHEN asked the Secretary of State for Scotland if, in view of the report of the condition of insanitary houses in Glasgow, he would consider the introduction of legislation to make it illegal for property owners to take rent for houses which had been declared unfit for human habitation by the sanitary authorities.—Sir JOHN GILMOUR replied: Local authorities already have statutory powers to deal with houses unfit for human habitation either by requiring the owners to make them habitable, or by closing and demolishing them. In the circumstances I am not prepared to consider the introduction of further legislation on the subject.

THURSDAY, JULY 7TH.

FINANCE BILL.

The House went into Committee on the Finance Bill, Captain FITZROY (Deputy Chairman of Committees) in the chair.

Mr. MACQUISTEN moved a new clause to provide that the duty on whisky should be reduced from its present figure of £3 12*s.* 6*d.* to £1 10*s.* He said that if he thought that this proposal would affect the revenue he would bring it forward with some diffidence in the present state of the country's finances; but he was satisfied if they sold whisky at 6*s.* per bottle instead of 12*s.* 6*d.* the consumption would be increased at least three times, and the Chancellor of the Exchequer would gain 90*s.* in place of his present 72*s.* 6*d.* As to the effect of whisky on the health of the people, that spirit was first invented by the clergy in the twelfth century, and at that time was largely used as medicine. They read of James V. giving so many bushels of barley to the monks of Dryburgh to make the "spirit medicine." Whisky was still very largely used as a medicine. It was a poison, but a slow poison, which killed the microbes of diseases. He remembered in 1918 an influenza epidemic taking place in a mine in South Africa with which he was connected, and during that epidemic they lost over 100 of their coloured labourers and none of the white staff. He said to the doctor: "You have a wonderful record in regard to the white workers, why could you not save the blacks?" and he replied: "I had not enough whisky to save the black men. By the time I had poured it down the whites there was very little left for the negroes, although a few of them were saved who got some for acting as undertakers." In 1920, when the Local Veto Bill was before Parliament, a police constable in the House of Commons said to him: "A dreadful thing is going to happen in Scotland. We live 50 miles away from a doctor and my mother always keeps a couple of bottles of whisky in the house. If any members of the family are taken ill they get half a bottle of whisky and they get better. We may not get it now."

Mr. JOHNSTON: Will the hon. Member explain why it is that insurance companies will insure a man's life at 10 per cent. less premium if he is a total abstainer?

Mr. MACQUISTEN said that those who insured their lives might give an undertaking to be total abstainers, but it never got any further than an undertaking. Continuing, the hon. Member said that out in the East there was a very large trade for whisky for sanitary reasons. It was a disinfectant, and everybody consumed it. There were no teetotallers there, because they all died very quickly. He expected that he would get from some of the members of the Labour Party stories as to the gaols and lunatic asylums which were being filled with drunkards. He was talking in the north to a leading alienist, and he put that question to him. The doctor replied: "It is all nonsense. Feeble-minded people take to drink because they are feeble-minded; they are not feeble-minded because they have a drink."

Mr. R. MCNEILL (Financial Secretary to the Treasury) said that he could give a very short answer to his hon. and learned friend. He was not called upon as representing the Treasury to go into the various questions as to the comparative values of whisky and other commodities. He looked at the thing from a purely financial point of view. This clause which Mr. Macquisten asked the Committee to accept would involve a loss to the Exchequer of something over £18,000,000. In order to neutralise the financial loss which this clause would entail to the Exchequer they would have to have an increase of 130 per cent. in consumption, and if his hon. and learned friend could be serious for two minutes he asked him to consider seriously whether they could face with equanimity an increase of 130 per cent. in the consumption of whisky next year? He hoped that the Committee would silently pass a vote of thanks to Mr. Macquisten for his entertainment, and let them get on to something else.

The clause was negatived without a division.

Major HILLS moved a new clause allowing an income-tax payer to deduct from his income-tax assessment expenditure due to the confinement of his wife, including the fees of physicians and nurses, and other costs immediately attributable to the confinement. He said that the deduction he proposed would be allowed whatever might be the number of children in the family. It became an increasing benefit not according to the wealth or position of the parent, but according to the number of the family. This was meant as an encouragement of children. The class at the bottom of the income-tax ladder was a very valuable class. It represented people on their way up in the world, and it was very important that they should be encouraged and produce children. The cost of confinement was a very heavy cost, and a bigger proportionate cost to parents with small incomes. Though parents with small incomes might not have an expensive doctor and nurse, the proportional cost was much greater.

Mr. R. MCNEILL said he must resist the clause. He could not see any reason why Major Hills desired to move the clause, which seemed to be a sort of converse to birth control, for his purpose here was to encourage an increase in the population. However desirable it might be to do that, it was not the function of the Treasury.

Lieut.-Commander KENWORTHY: Why do we have children's allowances at all?

Mr. R. MCNEILL said that children's allowances were not made for the purpose of encouraging large families; they were made to enable the parent of the family to discharge his duty to the Government, which was quite a different thing. This clause was an encouragement to people to be very reckless in regard to the class of medical attendance, nursing and nursing homes, which they selected. They would go to a very fashionable ladies' doctor and a very fashionable neighbourhood, and take very expensive rooms in a nursing home in Cavendish-square, and all the expense of this his hon. friend wished, to a certain extent, to be borne by the State through a deduction from income-tax. He saw no reason whatever for that. Why, if a man was to be assisted in this way on account of the confinement of his wife, should he not get similar assistance in other illnesses, much more dangerous and probably more onerous from the financial point of view. He hoped the Committee would support the Government in refusing this request.

The clause was negatived without a division.

Sir F. MEYER moved a new clause to provide that licence-holders of off-licences should be permitted to sell half-bottles of spirits. He said that as the law stood at present anyone who desired to buy less than a bottle of whisky or a bottle of brandy or other spirits was obliged to go to a public-house. That seemed to him to be a very curious and anomalous law. The supposed justification for it was that on-licence holders paid a considerably higher rate of duty than the off-licence holder. There might have been some justification for this point of view in former days, but now, when whisky cost 12*s*. 6*d*. per bottle, and brandy anything from 15*s*. a bottle, and a half-bottle cost 7*s*. or more, no one could say that permission to go to the grocer or the wine merchant to buy half a bottle of spirits would encroach severely on the rights of the publican to sell small quantities for on- or off-consumption for which he paid a higher duty. It had also been argued that the present system was in favour of temperance. But it seemed to him a very curious suggestion as a temperance argument that people should be compelled either to buy more spirits than they intended from the off-licence holder, or alternatively should go to the public-house for what they wanted.

Mr. R. MCNEILL said that there was little or no evidence of a sense of grievance or any public demand for a change in this matter. He agreed that on-licence holders all over the country were keen to get this particular restriction swept away, but that did not amount to what was called public opinion. He had a deputation before him at the Treasury on this subject more than a year ago, and all sorts of reasons were put forward. One specially urged was that in time of genuine sickness very often a person was ordered a little brandy, and it was very hard lines if he could not get a small quantity at a grocer's shop, and had to submit to the indignity of going to a public-house for it. When he suggested to the deputation that it would be possible to meet their view by making an exception in the case of brandy, that was immediately swept away and he was told that brandy had no particular medicinal value. His well-meant effort to meet a grievance was swept away, and he did not find then, and he did not find now, that there was any real grievance of which they were entitled to complain. He did not suggest that this clause should be rejected on the ground of any loss of revenue. But everyone knew that there was no more thorny question than the licensing law, and men of all parties once they began to operate on the licensing laws would find themselves in all sorts of pitfalls and difficulties, and hornets' nests, which they would do much better to avoid. He would, however, promise to ask the Chancellor of the Exchequer to reconsider this matter before the report stage, and if his right hon. friend found that it was possible for him to do so, he would then come to a definite decision.

Dr. WATTS said that he was not concerned with the on- or off-licence; he was only concerned with the comfort of the people. Reference had been made in that debate to the value of whisky or brandy in the treatment of disease. When he was in active medical practice some years ago he met with numerous instances of difficulties which were entailed by the operation of the law which this clause sought to remove. He had seen in his practice in days gone by scores of people, as in the great influenza epidemic, whose lives were entirely saved by the free administration of whisky or brandy. He was speaking from experience. He had known poor people who in times of stress and illness had had reason to get a small quantity of spirits, but they had had to go to off-licence premises and pay for a whole bottle. When the crisis was over they had been left with a large quantity of whisky, and in their natural satisfaction they had consumed the whisky, he was sorry to say, in some cases with bad consequences.

Sir F. MEYER offered to withdraw the clause, but a division was insisted on by the Opposition.

The clause was negatived by 170 votes to 80.

Bursitis among Miners.

Mr. TINKER asked the Home Secretary if he was aware that the miners were protesting against the description in the recent order issued by him dealing with industrial diseases under the Workmen's Compensation Act, which contained the definition subcutaneous cellulitis or acute bursitis arising at or about the knee (beat knee), subcutaneous cellulitis or acute bursitis over the elbow (beat elbow), as they were of opinion that the word acute should be struck out; and would he give further consideration to this question.—Sir WILLIAM JOYNSON-HICKS replied: Before issuing this order I considered a request from the miners to omit the word "acute." This request, however, was not supported by any evidence, and as the report published by the Medical Research Council showed that bursitis is not a disabling condition except when there is acute inflammation, I was unable to adopt the suggestion. I have received no further representations, and see no grounds at present for reconsideration.

Small-pox in England and Wales.

Dr. VERNON DAVIES asked the Minister of Health the monthly return of the number of small-pox cases certified in England and Wales, including London, from January, 1927; and the number of districts in which these cases had occurred.—Mr. CHAMBERLAIN replied: The following is the answer:—

Small-pox Cases Notified in England and Wales.

Four weeks ended	Jan. 29th	.. ..	2178 cases.
Four "	" Feb. 27th	.. ..	1808 "
Five "	" April 2nd	.. ..	2170 "
Four "	" April 30th	.. ..	1364 "
Four "	" May 28th	.. ..	1202 "
Five "	" July 2nd	.. ..	1200 "

These cases occurred in 214 sanitary districts. The figures are subject to revision.

FRIDAY, JULY 8TH.

INDIAN MEDICAL SERVICE.

The House went into Committee of Supply on the Civil Service Estimates for 1927, Mr. JAMES HOPE, Chairman of Committees, in the chair.

On a vote of £74,834 for a contribution towards the cost of H.M. Secretary of State for India in Council, including a grant-in-aid,

Earl WINTERTON (Under Secretary for India) said that some of the Indian local authorities had performed their duties satisfactorily while others had not done so. Many Indians, including Mr. Gandhi, had drawn attention to the delinquencies of some of these local authorities. The point was—and he would emphasise this as strongly as he could—that a great deal of the health and welfare of the individual Indian depended on how those authorities did their work, and the results, whether they were good or bad, mainly depended on the efforts of Indians themselves. In these matters they had Swaraj now and that was a fact which they should always bear in mind when they were discussing health matters—water-supply and things of that kind. After dealing with improvements which had recently been made in the housing conditions in Calcutta and Bombay, the noble lord said that he had seen returns from employers throughout India and these, though incomplete, indicated that, excluding some railways and Government concerns generally, no fewer than 348,000 workers were housed by employers. Over 700 employers provided doctors and dispensaries and about 300 maintained schools for employees or their children. They all knew that the death-rate of children under a certain age was high in India compared with this country, but it was not so generally known that the death-rate in those cities had been steadily decreasing, and the critics of the Government and of employers in India usually found it convenient utterly to ignore the other factors which came into the question of the infant death-rate beside those of housing and economic conditions, such factors as customs and traditions of the people, the marriage age, and the like. Every impartial observer who went among the people, and every doctor who attended them, knew their influence. He had already said that these customs had incurred condemnation, and indeed, castigation of prominent Indians in the Assembly and elsewhere; he would leave it at that, for it was really a question for Indians to deal with themselves. In these matters the Government could only advise and reform, where advice and reform were likely to be accepted by the communities concerned. It would be quite wrong to suppose that in any eastern country there

was the same urge for any authority, Government or local, to act as there was in Westminster. Anyone who believed the contrary was believing something which was utter nonsense. He might refer to what had been done for social service by such institutions as the Social Service League of Bombay, run very largely by Indians. He knew most of the people who ran it and very good work had been done by them. He might refer to what had been done by dispensaries for the supply of medicine and things of that kind, but he could only say that a great deal had been done. As regarded the recruitment for the services, he was able to report that the improvement which he noted last year had been continued. It was moving upwards in a steady curve. Last year 93 Europeans entered for the Indian Civil Service examination and this year the number was 112. It was a satisfactory feature that a number of Europeans had chosen the Indian Civil Service in preference to a career in the Home Civil Service. As regarded the army, the position there was better than it was when he last had occasion to deal with these estimates. It had been slowly but steadily improving, though they were not yet in the same happy position as they were in the matter of recruitment for the Civil Service, and they were not yet getting as many young officers as they required to maintain the establishment of the Indian army. The whole position was being very carefully watched by the Government of India and the Secretary of State, and all necessary measures would be taken to ensure that the recruitment of the British officers in sufficient strength would be adequately maintained in the future.

Sir RICHARD LUCE raised the question of the Indian Medical Service. He said he gathered that the long negotiations and the long consideration of the future of that Service were now almost completed. It was now over three years since the Lee Commission on the superior services reported on those services, and although the findings of that commission were largely implemented with regard to the other services they were left on one side with regard to the Indian Medical Service. He wished to refer to what was the very unsatisfactory condition of the present recruitment of that Service. From certain figures which had been supplied to him he found that at the present time there was a loss in the last five years of British medical officers in the Indian Medical Service of 61. That was an average of 12 British medical officers per year for the last five years. The present strength of the British members of the Indian Medical Service was 489 and that of Indians 158, to whom must be added 138 temporary Indian medical officers, leaving the proportion 1·6 British to one Indian. He understood from his noble friend that it had been laid down that for the efficient working of the Indian Medical Service there should be at least a proportion of two British to one Indian officer, and with the yearly loss of 12 officers that proportion which was already reduced to 1·6 to 1 must very rapidly deteriorate. It was laid down by the Lee Commission that it was necessary to maintain the definite proportion in the Indian Medical Service of British to Indian officers for two very important purposes, one of which was that the European officers serving in India as members of the Indian Civil Service and their families should have the advantage of having British medical officers attending them when they were ill. That seemed to him important and it was the idea of the Lee Commission. It was one of the ideas for the carrying on of the Indian Medical Service by British officers. The other requirement that was necessary was that there should be a sufficient reserve of British officers for the Indian army. That reserve was called upon to its very last ounce in the Great War, and it was absolutely essential if they were going to have the Indian army serve with the British forces wherever that might be that they should have a sufficient proportion of British medical officers among them to bring about a proper state of efficiency in that Service. Therefore it seemed to him that they were in a position of very considerable gravity with regard to the Indian Medical Service at the present time. They had already a proportion of British to Indian officers which was considerably below the proportion which was considered necessary for the efficient work of that Service, and they had further a very rapid rate of diminution on that percentage.

With regard to what might be the causes of the unpopularity—which was quite obvious—of the Indian Medical Service he was not able to say. There was, however, at the present time an unwillingness on the part of young doctors to go into any service abroad. Whether that was due to the loss of the spirit of adventure, or whether that spirit had been exhausted by the Great War, he could not say, but the fact remained that they had a very great difficulty in getting into the medical service, whether in the Army, Navy, Air Force, or the Indian forces, suitable medical candidates. He had gone carefully into the question whether that could have any connexion with the rates of pay, or the conditions of service, but he did not believe that it was at all due to that cause. The pay in the Indian Medical Service and the conditions of the Service compared favourably with the conditions in the other medical services at home. He thought that the great cause, apart from the one to which he had referred, was the spirit of uncertainty as to the future of the Service which they were joining, and he believed that if steps could be taken to get over that uncertainty, which was due to the very long delay in bringing to completion the negotiations as to the future of the Service, confidence would be restored and there would be a considerable possibility of getting recruits in future. If a campaign could be undertaken by the Government at the present time, and if the Under Secretary himself would visit some of the hospitals or encourage some of the officials who happened to be at home to go to the various hospitals in England to show the students that there was an assured future—which he believed was the case—for young medical men who joined the Indian Medical Service, a great deal could be done to get over the difficulty and to ensure a satisfactory recruitment. If he would undertake that he was sure that the noble lord would receive the support of the whole of the medical profession in England who looked with grave disquiet upon the unsatisfactory state of the Indian Medical Service.

Progress was reported and the debate was adjourned.

MONDAY, JULY 11TH.

Pension Rights of Indian Provincial Officers.

Mr. WARDLAW-MILNE asked the Under Secretary of State for India whether, now that orders had been issued by certain of the local governments extending to certain of the provincial service officers of non-Asiatic domicile some of the concessions recommended in the Lee Commission report, the question of the extension of the concessions to include the right to retire on proportionate pension would be considered.—Earl WINTERTON replied: My noble friend is not prepared to extend the right to retire on proportionate pension beyond the All-India services to whom the premature retirement rules apply, but he has directed the Government of India to notify local governments that he will be prepared to consider on their merits, as cases falling outside the rules, applications for permission to retire prematurely from officers serving under local governments who either (1) were appointed by the Secretary of State in Council, or (2) were appointed by a subordinate authority, but in the local government's opinion are deserving of special consideration.

TUESDAY, JULY 12TH.

Experiments of Dr. Voronoff.

Sir ARCHIBALD SINCLAIR asked the Secretary of State for Scotland whether his attention had been drawn to the experiments of Dr. Voronoff, who claimed greatly to have increased the size of sheep and wool production by gland operations; and whether the Board of Agriculture proposed to make any inquiry into these claims.—Mr. MACROBERT (the Solicitor-General for Scotland) replied: Yes, Sir. My right hon. friend is aware of the work of Dr. Voronoff. The Ministry of Agriculture, in conjunction with the Board of Agriculture for Scotland, propose to carry out an expert investigation of these experiments during the autumn.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. A. R. H. Skey to be Surg. Rear-Admiral and is placed on the retired list.

Surg. Capt. H. C. Whiteside to be Surg. Rear-Admiral.

Surg. Comdr. P. D. Ramsay is placed on the retd. list with rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

ARMY DENTAL CORPS.

Lt. G. A. Ballantyne (Temp. Flying Offr., R.A.F.) to be Capt.

ARMY RESERVE OF OFFICERS.

Capt. S. Robertson relinquishes his commn., and retains the rank of Capt.

DENTAL OFFICERS IN THE ROYAL NAVY.

The undermentioned were successful in the competition held on June 29th and succeeding days, for entry into the Royal Navy as Dental Officers, and will receive appointments as Acting Surgeon Lieutenants (D): Henry Arthur Ginn (Guy's Hospital), Harold Edward Rose (King's College Hospital), George Blackbarrow Fellows Reece (Royal Dental Hospital of London), Louis Victor Donegan (Incorporated Dental Hospital of Ireland), Herbert Vincent Pell (Royal Dental Hospital of London).

The King, on the occasion of the visit of the Duke and Duchess of York to New Zealand and Australia, has promoted Surg. Comdr. H. E. Y. White, M.V.O., O.B.E., R.N., Medical Adviser to His Royal Highness, to Commander of the Royal Victorian Order.

Medical News.

UNIVERSITY OF OXFORD.—At recent examinations the following candidates were successful in the undermentioned subjects :—

B.M. AND B.CH.

Medicine, Surgery and Obstetrics.—H. W. Allen, E. N. Butler, Rosalind V. Carruthers, C. Charleson, P. F. Cluver, C. L. Cope, W. N. Dickenson, J. L. Glover, R. C. Probyn-Williams, J. W. Pugh, and Irene M. Titcomb.

Pathology.—H. S. Atkinson, M. V. Bhajekar, B. R. Caygill, R. T. V. Clarke, T. L. Davies, S. B. Davis, A. J. Gibbs, H. P. Gilding, J. L. Glover, G. G. Hill, Florence H. Johnson, Caroline E. MacNeice, Q. St. L. Myles, R. C. Probyn-Williams, J. G. Reid, S. Segal, D. C. Shields, E. E. Swaby, W. J. Walter, and Joyce Wright.

Forensic Medicine and Hygiene.—D. H. Brinton, J. A. Brown, E. N. Butler, Rosalind V. Carruthers, T. L. Davies, S. B. Davis, J. L. Glover, G. G. Hill, A. P. Kingsley, R. L. P. Peregrine, and Irene M. Titcomb.

Materia Medica.—R. E. Adam, Annie Adams, G. Ashton, J. H. B. Beal, J. A. Brown, B. R. Caygill, J. L. Clapham, F. R. Crookes, W. T. Dawson, R. C. Garman, A. J. Gibbs, J. M. Gibson, T. N. Gledhill, W. H. Greany, R. M. J. Harper, H. M. Harris, A. L. Jacobs, J. M. Lees, W. H. McMenemey, G. B. Malone-Lee, W. H. Owles, J. H. Peel, J. G. Reid, C. R. Salkeld, D. C. Shields, and C. Wilson.

It is announced that John Hugh Bruce Beal, scholar of University College, has been elected to the Radcliffe Scholarship in Pharmacology, 1927.

The Theodore Williams Scholarship in Physiology has been awarded to A. L. Jacobs, Jesus College, and A. W. D. Leishman, University College, whilst the Theodore Williams Scholarship in Human Anatomy has been awarded to F. M. Trefusis, Exeter College, and M. W. C. Oldfield, University College. R. Pakenham Walsh, University College, receives the Welsh Memorial Prize for Anatomical Drawing.

UNIVERSITY OF ABERDEEN.—At a Graduation held on July 7th the following degrees and diplomas were conferred :—

D.Sc.—C. Reid, M.D., and J. Smith, M.D.

M.D.—*N. C. Simpson, J. T. Cameron, Maggie Florence Jane Moir, F. H. B. Norrie, H. G. Topping, and J. M. Whyte.

Ch.M.—M. M. Cruickshank.

* Awarded honours for thesis.

M.B. and Ch.B.—G. N. Clark, †G. M. Dean and ‡A. W. Forrest, Flora Leslie Baxter, W. J. Brenmer, Frances Elizabeth Bruce, Joan Gordon Thain Dunbar, R. T. Easton, A. F. Emmanuel, W. H. Emslie, J. B. Ewen, A. D. Forgie, O. M. Fraser, A. J. Gardiner, H. B. Giles, H. R. Harris, A. W. Henderson, E. A. Johnston, W. E. Johnston, J. W. Lyall, L. C. Lyon, W. C. McIntosh, D. B. Mackenzie, Mary Meta Mackenzie, I. Mackintosh, R. G. A. McLaren, E. W. Malcolm, A. W. Michie, G. Milne, J. W. Mitchell, W. E. Morrison, M. van Niekerk, J. Pennie, D. C. Rice, J. A. G. F. Rose, J. A. Sharkey, ‡R. G. Spink, R. D. Stuart, M. G. de L'Isle Sturm, ‡A. E. Thomson, ‡J. G. Thomson, W. R. Topping, A. W. West, and W. M. Wilson.

D.P.H.—F. J. T. Bowie, S. V. van Niekerk, A. D. Rankin, Margaret Elizabeth Rankin, and W. D. Whamond.

† Completed Final Medical Professional Examination with much distinction.

‡ Completed Final Medical Professional Examination with distinction.

UNIVERSITY OF MANCHESTER.—Dr. H. B. Maitland has been appointed professor of bacteriology and director of the department of bacteriology and preventive medicine in succession to Prof. W. W. C. Topley.

Dr. Maitland graduated in medicine and surgery in the University of Toronto in 1916 and obtained the degree of M.D. by thesis in 1922. He qualified as M.R.C.S. Eng. in 1918. From 1917 to the end of 1918 he served in the Royal Navy as surgeon-lieutenant, and from 1919 to 1921 was lecturer in bacteriology in the University of Toronto. In 1921 he was appointed associate professor in that university and occupied this position until 1924. After six months spent in visits to the principal bacteriological departments in Germany, he was appointed early in 1925 to assist in the research upon foot-and-mouth disease, later taking charge of the investigations done for the Commission. He was subsequently elected to the staff of the Lister Institute, where he is at present engaged upon research.

At recent examinations the following candidates were successful :—

FINAL EXAMINATION FOR M.B. AND CH.B.

Dorothy Arning, H. Arstall, A. H. Baker, R. H. Barnes, R. H. Blackburn, Dorothy M. Bradley, H. J. Brennan, J. W. Brooks, Lillie M. Burton, Louie J. Burton, Muriel M. Edwards, J. S. Goller, A. Hancock, Zaky Hanna, † G. Metcalfe, R. Newton, G. L. Normington, R. P. Osborne, H. A. Palmer, L. C. Peringuey, † G. H. Racklyeft, Norah Regan, M. Robinson, Eleanor B. Schill, A. Thomas, R. H. Tootill, H. Townley, Vera Urmson, F. F. Waddy, G. R. Walker, Josephine Walmsley, and *K. H. Watkins (with second-class honours).

* Distinction in Medicine.

† Distinction in Forensic Medicine.

The following have satisfied the examiners in the undermentioned parts of the examination :—

Forensic Medicine.—S. K. Appleton, Doris Bernard, R. Edmondson, and J. H. Jones.

Hygiene and Preventive Medicine.—R. S. Abraham, S. K. Appleton.

Obstetrics and Surgery.—S. K. Appleton, H. J. Brennan, E. H. Brooks, Agnes M. Buckley, E. Cretney, E. B. Davies, Mary G. Davies, Dorothy Guest, G. B. Hardman, Amy H. Herbert, J. A. Longworth, Jean M. Marshall, J. W. Murray, J. R. Nuttall, J. F. O'Grady, S. L. Rowley, Lucy Stokoe, A. Thomas, R. H. Tootill, Vera Urmson, J. Vine, and G. R. Walker.

Obstetrics.—D. E. Francis and Kathleen McGowan.

THIRD EXAMINATION FOR M.B. AND CH.B.

Pathology.—W. S. Ramsden.

Pharmacology.—W. W. Fox and A. Taylor.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Mary C. Luff.

DIPLOMA IN BACTERIOLOGY.

N. A. Arnold, Phyllis M. Congdon, Margaret Pownall, W. Smith.

DIPLOMA IN PUBLIC HEALTH.

Part I.—W. C. V. Brothwood, J. Cumming, Miriam Florentin, T. S. Hanlin, H. Harrison, Fanny Howe, M. V. Menon, T. Pierson, Marjorie Reekie, and S. P. Wilson.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful :—

M.D.

W. Emdin, S. M. Katz, and J. A. Scott.

M.B. AND CH.B. (WITH HONOURS).

Class I.—W. S. Brindle, J. McHugh, S. P. Meadows, and A. D. Polonsky.

Class II.—J. K. Cameron, A. Dodd, P. H. Whitaker, and R. L. Wynne.

FINAL EXAMINATION FOR M.B. AND CH.B.

Part III.—T. Blezard, J. H. Boultbee, H. C. Calvey, K. M. Cobban, E. Cohen, F. R. Craddock, W. J. Eastwood, L. S. Goldman, J. G. Hattingh, H. E. Hughes-Davies, E. D. Irvine, O. V. Jones, Theresa J. Lee, J. L. Lewis, F. E. Lomas, J. W. Melville, E. P. Moloney, Edna Morris, C. Rigby, N. W. Riley, J. B. Rushton, Alfreda H. Slater, V. J. M. Taylor, J. P. Thomas, D. P. de Villiers, A. J. Walsh, and E. N. Wardle.

Part II.—S. Alstead, E. T. Bates, R. K. Bowes, J. H. St. B. Crosby, T. B. Davie, R. Doyle, H. R. Dugdale, J. P. Flanagan, J. H. Follows, Agnes G. Gillespie, R. G. Gornall, E. W. Jones, Mary G. Jones, W. E. J. Jones, N. R. Lawrie, J. M. Leggate, H. Leiper, J. S. Mather, C. T. Mercer, Winifred O'Callaghan, H. Paterson, E. L. Rubin, H. W. Smith, G. G. Warburton, and F. J. Welton.

Part I.—A. E. Adams, S. W. Adler, A. E. Carrol, E. Cook, J. E. Jones, N. W. Roberts, G. A. Talwrn-Jones, and A. L. Williams.

DIPLOMA IN PUBLIC HEALTH.

Eudora V. Beatty, Helen S. H. Brown, M. S. Grutu, R. C. Gubbins, and Isabel McKee.

DIPLOMA IN TROPICAL HYGIENE.

C. P. Allen, G. A. Dunlop, J. Harkness, R. Hay, Kathleen Hyslop, J. Macdonald, A. J. Murray, H. M. Nevin, and R. Walkingshaw.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on June 22nd it was resolved to institute an academic diploma in bacteriology, the regulations for which may be had from the Academic Registrar.—The University studentship in physiology for 1927–28 was awarded to Mr. H. B. A. R. Densham, B.Sc., of Guy's Hospital, who proposes to complete his medical course and to continue investigations on the circulation through the skin and on cardiac dyspnœa which he is carrying out under the direction of Prof. Pembrey.—The University medal at the M.B., B.S. examination held in May, 1927, has been awarded to Max Barer, of University College Hospital.—Applications are invited for the William Julius Mickle Fellowship, of the value of at least £200, which is awarded annually to the man or woman who, being resident in London and a graduate of the University, has in the opinion of the Senate, done most to advance medical art or science within the preceding five years. Applications must be made in form to the Principal Officer of the University not later than Oct. 1st.

University College.—In connexion with the centenary of Universty College a fund of £500,000 is being raised to meet the need for further endowment, and for buildings and equipment. The amount raised up to June 18th is £117,440, which includes about £43,000 contributed by past and present students, and a grant of £25,000 by the Rockefeller Foundation for the endowment of the Department of Pharmacology. The same Foundation has also allocated £93,178 to form a further endowment fund, supplementary to that of 1921, for the Departments of Anatomy and Physiology, the work and progress of which have necessitated a larger expenditure than was anticipated in 1921.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the annual election of Fellows into the Council held on July 7th, the President, Sir Berkeley Moynihan, presiding, there were nine candidates for three vacancies. The following is the result of the election: Sir Cuthbert Wallace (489 votes) and Mr. William Thelwell Thomas, M.B.E. (475) votes, were re-elected, and Mr. Hugh Lett (366 votes) was elected a member of the Council. The unsuccessful candidates were: Mr. L. P. Gamgee (344 votes), Mr. C. C. Choyce (328 votes), Sir Crisp English (314 votes), Mr. J. P. Lockhart-Mummery (224 votes), Mr. H. J. Paterson (158 votes), and Mr. H. W. Carson (153 votes). Mr. H. J. Price and Mr. Wilmott Evans acted as scrutineers.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—A reception was held at the College on Friday evening, July 8th, in celebration of the centenary of the discovery of Bright's disease. The President, with Lady (Rose) Bradford, received the guests in the library, among whom were the official representatives of the various countries present in London to do honour to Bright's memory. In the theatre an interesting exhibition was given of cinematograph films by the Provincial Cinematograph Theatres, Ltd., the films provided being demonstrations in natural history, such as the evolution of the caddis and may-flies, the life story of a puss-moth, and the life contents of a wineglass aquarium. Refreshments were served in the reading-room, and the College was crowded till a late hour.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Friday, July 22nd, at 5 P.M., at the Royal Westminster Ophthalmic Hospital, Mr. W. H. McMullen will give a lecture-demonstration on Some Causes and Effects of Defective Vision in Children. This will be free to all members of the medical profession. During August there will be two special courses. The first, at the Infants Hospital, Vincent-square, will be from August 8th to 21st, from 2 P.M. daily, in Diseases of Infants. On both Saturdays and one Sunday special visits have been arranged. (Fee for the course, £3 3*s*.) The second course, from August 29th to Sept. 10th, will be held at the Queen Mary's Hospital for the East End, Stratford, and will occupy most days from 10 A.M. to 5 P.M. It will include demonstrations of medical, surgical, orthopædic, ophthalmic, obstetric, and ear, nose, and throat cases, besides operations and lectures. (Fee, £3 3*s*., or £2 2*s*. for either week.) Besides these special courses, there is always the general course of work in the associated hospitals. For this a comprehensive ticket is issued for any period from one week to one year, and the post-graduate is left to make up his time-tables from the programme of clinics given. Copies of all syllabuses are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W., who can supply information on post-graduate work in London and the provinces.

BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH.—At a recent meeting of the trustees, Dr. H. H. Dale, secretary of the Royal Society, was appointed a member of the advisory board in place of the late Prof. E. H. Starling. Sir James Kingston Fowler (hon. secretary) presented the annual report, in which reference was made to the increase of the annual value of the Fellowships announced last March. As from Oct. 1st, their value will be: Junior Fellowships, £400; Fourth Year Fellowships, £500; and Senior Fellowships, £700. Mention was also made of the trustees' decision to institute a Research Fellowship in Tropical Medicine of the annual value of £1000 and tenable for five years. This has been awarded to Mr. Edward Hindle, Ph.D., who was an original Beit Fellow (1910–12) and served with the Kala-azar Commission of the Royal Society to North China (1925–27). He will work on spirochætosis, with special reference to the causation of yellow fever. A Junior Fellowship in Tropical Medicine has been awarded to Dr. Henry Pollard Hacker, who will work on problems in the prevention of malaria. Mr. Alan Sterling Parkes, Ph.D., Miss Honor Bridget Fell, Ph.D., and Miss Margaret Averil Boas, Ph.D., have been promoted from Junior Fellowships to Fourth Year Fellowships, and Mr. William Kershaw Slater, M.Sc., has been promoted from a Fourth Year to a Senior Fellowship. The following appointments to Junior Fellowships are announced for research in the subjects indicated: Frank Robert Winton, M.D. Camb., assistant to the Department of Pharmacology, University College, London: (*a*) Urinary secretion; (*b*) Physiology of plain muscle. Walter Reginald Wooldridge, M.R.C..V.S., Frank Smart Student at the Sir William Dunn Institute, Cambridge: Bacterial chemistry in relation to immunity. Walter Thomas James Morgan, M.Sc., Biochemical Research Student at the Lister Institute, London: Structure of hexose phosphoric acids. Philip Eggleton, M.Sc. (University College, London), working for the Medical Research Council: Carbohydrate metabolism of contractile tissues; comparison of different types of contractile tissue. Guy Frederic Marrian, M.Sc., assistant in Department of Physiology, University College, London: Vitamin B; the adrenal glands. Archibald Roderick Fee, B.A., engaged in research at University College, London: Renal metabolism. Mr. Francis William Rogers Brambell, who was nominated for a Fellowship, withdrew shortly before the election, having received an offer of a teaching post at a university.

Correspondence concerning the Fund should be addressed to the hon. secretary, Beit Memorial Fellowship, 35, Clarges-street, London, W.1.

MANCHESTER ROYAL INFIRMARY.—The James Bathgate Dickinson Scholarships have been awarded to Dr. R. W. Fairbrother (Travelling Research Scholarship in Medicine), Dr. F. H. Smirk (Scholarship in Pathology), and Dr. F. Livesey (Scholarship in Anatomy).

INTERNATIONAL HOMŒOPATHIC CONGRESS.—This congress will be held in London next week. A meeting will take place at the Mansion House on Monday, July 18th, at 5 P.M., and there will be daily sessions at the Connaught Rooms, Great Queen-street, W.C. 2. The organising secretary is Dr. H. Fergie Woods, 93, Harley-street, W. 1.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, July 19th.—5.30 P.M., GENERAL MEETING OF FELLOWS: Ballot for election to Honorary Fellowship.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, July 18th, to SATURDAY, July 23rd.—FELLOWSHIP OF MEDICINE DEMONSTRATIONS. Fri., 5 P.M., Mr. W. H. McMullen on "Some Causes and Effects of Defective Vision in Children" at the Royal Westminster Ophthalmic Hospital. Open to all members of the medical profession without fee.—PARK HOSPITAL, Hither Green, S.E. Post-graduate course in Infectious Fevers. Wed., 2.30 P.M., and Sat., at 11 A.M.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Lecture-demonstrations daily, 5 P.M., throughout the month. Further information from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, July 18th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, July 19th.—3.15 P.M., Dr. C. Gouldesbrough: The Scope and Limitations in Modern X Ray Therapy.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, July 18th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Donald Armour: Operations.
TUESDAY.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients. 3 P.M., Dr. Pritchard: Medical Wards.
WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Mr. Gibb: Eye Department.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 3 P.M., Sir Henry Simson: Gynæcological Ward.
FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Operations. Mr. Vlasto: Throat, Nose and Ear Department.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy and Ward List. 10 A.M., Dr. Owen: Medical Diseases of Children.
Operations, Medical, Surgical, and Special Out-patients daily, 10 A.M. to 5 P.M.; Saturdays, 10 A.M. to 1 P.M.

Appointments.

CAPPS, FREDERICK C. W., F.R.C.S. Eng., has been appointed Surgeon to the Ear, Nose and Throat Department, with charge of Out-patients, Willesden General Hospital.

FERGUSON, D., M.B., Ch.B. Glasg., Medical Officer of Health for the Burgh of Motherwell and Wishaw.

OWEN, DAVIES CHARLES, M.B., B.S. Lond., F.R.C.S. Eng., Honorary Assistant Surgeon at Stanley Hospital, Liverpool.

Certifying Surgeons under the Factory and Workshops Act: McCOOL, P., M.B., Ch.B. Edin. (Chepstow); JEFFERIS, I. M., L.R.C.P. Lond., M.R.C.S. (Totnes).

Medical Referees under the Workmen's Compensation Act (Metal Grinding Industries (Silicosis) Scheme): NAISH, A. E., F.R.C.P. Lond., BARNES, A. E., F.R.C.P. Lond., MACADAM, W., M.D. Glasg.; MARSDEN, R. W., M.D. Manch.; DICKINSON, W. H., M.D. Edin.; HEASMAN, H. W., L.R.C.P. Lond., M.R.C.S.; and BALL, L., M.D. Lond.

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal United Hospital.—Asst. H.S. £100.
Beckenham Urban District Council.—M.O.H. and School M.O. £900.
Bedford County Hospital.—Asst. H.S. £130.
Bolton, Townleys Hospital, Farnworth.—Second A.M.O. £225.
Bradford Royal Infirmary.—Two H.S.'s. £150 each.
Brighton, Royal Alexandra Hosp. for Sick Children.—H.P. £100.
Buxton, Devonshire Hospital.—A.H.S. At rate of £150.
Cambridge, Papworth Sanatorium and Village Settlement.—H.P. At rate of £100.
Elizabeth Garrett Anderson Hospital, Euston-road.—Asst. Obstet.
Evelina Hospital for Children, S.E.—H.S. £120.
Exeter, Royal Devon and Exeter Hospital.—H.P. At rate of £130. Also Hon. Surg. Dentist.
Hertford County Hospital.—H.S. At rate of £150.
Hull Royal Infirmary.—Asst. H.S. £150.
Ilford Borough.—Chief Asst. M.O.H. £700.
Indian Medical Service.—Appointments.
Lewisham Hospital.—Asst. M.O. £300.
Liverpool Eye and Ear Infirmary.—H.S. £100.
Manchester, Ancoats Hospital.—Pathological Registrar. At rate of £100. H.P. At rate of £100.
Manchester Hospital for Consumption.—Hon. Anæsthetist.
Manchester City.—Asst. Tuberculosis Officer. £650.
Royal Free Hospital, Gray's Inn-road, W.C.—First and Second Cas. Officers.
Royal Northern Hospital, Holloway.—Med. Registrar. £100.
Royal Waterloo Hospital for Children and Women.—Hon. Radiologist. Hon. Gynæcologist.
St. Mary's Hospital for Women, Plaistow.—R.M.O. and A.R.M.O. £175 and £130 respectively.
Salford Education Committee.—Asst. School Med. Officers. £600 each.
Samaritan Free Hospital for Women.—H.S. At rate of £100. Also Hon. Surg.
Sheffield Royal Hospital.—Res. Ophth. H.S. At rate of £80.
Sheffield Royal Infirmary.—Hon. Asst. Ophth. S.
Staffordshire General Infirmary, Stafford.—H.P. At rate of £150.
West London Hospital, Hammersmith-road, W.—Res. Asst. S. £200.
Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £300.

Births, Marriages, and Deaths.

BIRTHS.

BLIGH.—On July 10th, at 74, Rodney-street, Liverpool, the wife of John Murray Bligh, M.D. Liverp., M.R.C.P. Lond., of a son.
KIDD.—On July 5th, at Leeds-road, Harrogate, the wife of W. Shirley Kidd, M.B., B.S., of a son.
MILLIGAN.—On July 4th, at Belle-avenue, Reading, the wife of H. J. Milligan, *M.C.*, M.D., of a son.
MORRIS.—On July 5th, at the Rectory, Stradbally, Co. Waterford, Irish Free State, the wife of Major C. R. Morris, D.S.O., R.A.M.C., of a daughter.
ROBERTS.—On July 5th, at a nursing home, Darlington, the wife of David R. E. Roberts, M.B., B.Ch., of a daughter.
THOMAS.—On July 4th, at Lancaster Gate, W., the wife of Dr. Cyril J. Thomas, of a son.

MARRIAGES.

GILCHRIST—SAMPSON.—On July 5th, at All Souls', Langham-place, London, W., Adam Gilchrist, M.B., Ch.B. Aberd., of Burslem, Staffordshire, to Winifred Mary Sampson, M.B., B.S. Lond.
HUNT—NICHOLAS.—On July 6th, at Southwark Cathedral, William Stanley Hunt, B.Chir. Camb., to Jane Gwyneth, eldest daughter of Mr. and Mrs. John Nicholas, of Llandovery.
MOORE—FERGUSSON.—On July 4th, at the Parish Church, Bushey, Richard Henry Moore, M.B., B.Ch. Belf., of Upper Wandle House, Wandsworth, to Helen Edith Fergusson, M.B., B.S. Lond.

DEATHS.

BAYLISS.—On July 6th, at Mountnessing Weston, Bath, Richard Arthur Bayliss, M.R.C.S. Eng., L.R.C.P. Lond., aged 60.
CAMPBELL.—On July 10th, at Clarendon-terrace, Dundee, Alexander Campbell, M.D., F.R.C.S., in his 86th year.
HULKE.—On July 1st, in London, Frederick Malcolm Stirling Hulke, M.R.C.S. Eng., L.R.C.P. Lond., aged 39.
SMYTH.—On July 2nd, at Apsley-road, Clifton, John Smyth, M.D., Colonel, I.M.S., aged 69.
THOMAS, THELWALL.—On July 7th, 1927, at Verdala Tower, Allerton, Liverpool, Anabel Roxburgh, the wife of W. Thelwall Thomas, Surgeon, and daughter of the late Alexander Spence, of Huntly, Aberdeenshire.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

PUBLIC HEALTH IN SHANGHAI.

IN a recent account of the health of the British troops in Shanghai (THE LANCET, 1927, i., 1319) mention was made of the work being done by the municipal department of public health. This department has now published its annual report for 1926, containing a review of the sanitary conditions prevalent in the foreign settlement. At Shanghai there are, on the one hand, over 800,000 Chinese and 23,000 foreigners living under the ægis of a well-ordered international municipal council; on the other, a larger mass of natives (1,150,000) living in overcrowded insanitary conditions under Chinese jurisdiction. A comparison of the two systems shows a glaring inequality.

The two leading features of the year were an exceptionally hot and humid summer with a rainfall of 51·89 inches and an outbreak of cholera which became epidemic during July, when it reached its peak, 692 cases being notified. Virulent scarlet fever occurred throughout the year, and small-pox prevailed till the end of July, after which, curiously enough, not another case was notified. Shanghai maintained its freedom from plague epidemic; one plague-infected rat was found and, as in former years, no time was lost in carrying out intensive anti-plague measures. There were two fatal cases of anthrax, attributed to cheap shaving-brushes.

The deaths of 615 foreigners were reported, giving a rate of 20·12 per 1000 as compared with 16·24 in 1925. The majority of the deaths (62·9 per cent.) occurred among Asiatics other than Chinese, 55·4 per cent. being Japanese. The principal communicable diseases accounting for the increased death-rate were typhoid fever, amœbic dysentery, acute diarrhœa, small-pox, scarlet fever, and measles, a noteworthy feature being the great increase of deaths among children between the ages of 1 and 5 years. Altogether 12,326 Chinese deaths were recorded, compared with 8936 in 1925, giving a death-rate of 15·35 per 1000, the highest rate since 1914. This points to the fact that Chinese are the prey of adverse climatic conditions to the same extent as foreigners.

The report gives a number of detailed statistical tables showing the close track that is kept of the incidence of disease and the causes of death. Every effort has been made to obtain the compulsory registration of medical practitioners, of whom there are 145 (including 24 British), but the council has as yet no legal authority to enforce this. A system of voluntary registration has been evolved by the help of which the public health department can have more definite information as to the number of births and deaths and the notification of communicable diseases; 713 cases of notifiable diseases among foreigners were reported voluntarily.

As is well known small-pox is endemic in China, but though frequent warnings are issued concerning the serious danger of bringing unvaccinated employees to the East, this advice is often ignored. A total of 48,824 vaccinations was performed by the public health department and there were 38 cases of small-pox among foreign residents with 12 deaths; eight of those who died had not been vaccinated, one had been vaccinated in 1901, one was vaccinated three days before the onset of the disease, whilst in the remaining two cases there was no reliable history. There were 31 deaths from typhoid and paratyphoid among foreigners, besides 20 fatal cases of amœbic dysentery and seven of bacillary dysentery; 27 cases of diphtheria and 132 cases of scarlet fever among foreigners were notified, and in both diseases it was observed that the outbreaks were most prevalent from January to June and waned with the advent of hot weather.

Cholera has been prevalent 14 times during the past 24 years, but shows no evidence of cyclical periodicity. It is noteworthy that when absent in Shanghai it has been epidemic in other parts of China, notably in districts affected by famine. Cholera is endemic in the Yangtze Delta, a vast plain several thousand square miles in extent, with a population of over 20 million people, Shanghai being the most thickly populated area in the Delta. A network of tidal and semi-tidal creeks drains into the Huangpu River on the banks of which Shanghai is situated and the difficulties of the situation are thus greatly enhanced, for the International Settlement is completely surrounded by territory over which it has no jurisdiction. Altogether 3216 cases were notified and of this number 76 were among foreigners, and in 57 the diagnosis was confirmed by bacteriological examination. The most intense focus of infection in the International Settlement adjoined the Chinese district of Chapei. The water-supply of the Chapei Waterworks Company came under suspicion and samples from the intake, the filter beds, and the taps from the mains were

examined in the municipal laboratory of the International Settlement. In every case cholera vibrios were found to be present. Prompt measures for the purification of the Chapei water-supply were immediately followed by decline of the epidemic.

Of 228 specimens of blood examined for malaria only 31 gave positive results; all the parasites found belonged to the benign tertian group. This disease seems to be uncommon in Shanghai, but with the advent of so many troops from India this year it will be interesting to note if there is any increase in malarial infection, and if malaria of other types will become manifest when the mosquito season begins this month.

A large number of chemical (2905) and bacteriological (10,206) analyses and examinations were made. Water, milk, foods, and liquors are frequently tested for purity. The report concludes with accounts of the hospitals, gaols, and markets which come under the purview and close supervision of the Commissioner of Public Health, Dr. C. Noel Davis, and his staff. Of recent years there have not been wanting signs that the Chinese authorities have been willing to learn the lesson at their doors as to the benefits arising from efficient public health measures, but the frequent changes of Government have, for the present at any rate, resulted in a state of chaos in which there is neither time nor room for any thought about the health of the people outside the Settlement.

THE TRAINING OF DEFECTIVE CHILDREN.

ON July 5th Madame Montessori gave a lecture in Italian —which was translated by an interpreter—on the Training of Defective Children, in aid of the Royal Free Hospital Appeal Fund. In her opening words the lecturer stressed the fact that the education of the mentally deficient child did not differ fundamentally from that of the normal one. She explained how her own research had been undertaken first on behalf of the mental deficients, and how many of the discoveries she had made, such as the importance of touching and handling as aids to learning, had proved of equal value to all. But whereas the normal child could learn and develop in spite of unfavourable environment, the mentally defective could not, just as the deaf child would also be dumb without specialised speech training. It was of particular importance to take advantage of the "sensitive periods" in the child's mental life, and to employ most careful and thorough indirect preparation for each step onwards throughout his education. Graphs were shown illustrating the progress of children in an institute under the Montessori system. These made it plain that a high level of achievement was maintained throughout, as distinct from the irregularity shown under other systems. Madame Montessori maintained that a high percentage of mentally deficient children were eventually capable of filling a useful place in the world.

WANTED—AN EXPLANATION.

To the Editor of THE LANCET.

SIR,—The case cited by Dr. A. T. Schofield in your issue of July 2nd (p. 52) interests me greatly, and I put forward what seems to me a quite feasible if not probable explanation. During the days following the accident the wound apparently went through the ordinary process of healing, with the usual subsequent formation of scar tissue. Normally the nail takes about nine months to grow from base to tip. I suggest that, in this case, as the nail grows forward the vis-a-tergo is not strong enough to force the nail onward against this obstruction of the fibrous barrier. The growth of the nail is thus arrested until the distal portion is shed. The distance of the lesion (about a quarter of an inch) from the tip of the finger determines the regular intervals of recurrence.

I am, Sir, yours faithfully,

E. HOPE JOHNSON, M.R.C.S.

West Middlesex Hospital, Isleworth, July 6th, 1927.

A USEFUL DIRECTORY.

WE are always glad to see an up-to-date copy of Webster's Royal Red Book, the 269th edition of which was published in January and the 270th in May. All possible care is taken, it is stated, to ensure correctness, and it is convenient not have to wait 12 months for a new issue. There is a street guide, an alphabetical list, and lists of Members of the House of Peers and House of Commons, of Government offices, and of public societies and institutions. A special feature is a large section containing plans of well-known London theatres. There are many useful advertisements in the handbook and a selected list of Royal Warrant holders; but we should hardly be likely to find among them such a one as we saw in the 1837 edition of Boyle's Court Guide (now incorporated with Webster's Royal Red Book) in which a man claimed the title of "Bug Catcher to His Majesty" (William IV.).

NATURAL SUN-THERAPY IN ENGLAND.

THERE is general agreement that exposure to the rays of the sun exerts a beneficial action upon surgical forms of tuberculosis. There is less unanimity about its value in pulmonary tuberculosis, and owing probably to the difficulty in selection of suitable cases, and the ease with which an overdose can be administered, sunshine is regarded in many quarters as useless or even harmful in the treatment of consumption. Experiments carried out by Dr. J. E. Wood at the Bramshott Sanatorium for Sailors have, however, led to such encouraging results that the Seamen's Hospital Society have decided to arrange for a further trial of the method. They have accordingly built and equipped a large ward, with walls of Vita glass, at their sanatorium, so that controlled sunning may be carried out at any time of day and at any season. Shelter from wind and shower is thus provided without restriction of the limited sunshine that this country enjoys. It is hoped that not only will the merchant seaman derive benefit therefrom, but useful data will be collected regarding the possibilities of using sunshine and skyshine in this country in all forms of tuberculosis and in all classes. The new ward will be formally opened by Admiral Sir Montague Browning on Monday next, at 3.30 P.M.

THALLIUM ACETATE.

IN the official bulletin for 1927 of the Department of Health of Mexico Dr. Margarita Delgado describes experiments to determine the effects of thallium salts on the animal body and especially their toxic dose, oral and hypodermic. The salt used was the acetate, mixed with some oxide; the mixture takes up water rapidly, which perhaps accounts for the differences in the toxic dose met with by various observers. Doses of 0·014–0·018 g. per kg. of body-weight were toxic to animals, but doses of 0·008 g., which is the maximum employed therapeutically, had no ill-effects. Doses of more than 0·014 g. per kg. were almost invariably lethal to rabbits and guinea-pigs, the main lesion being an acute tubular nephritis; with doses between 0·014 and 0·012 g. the animals lived for a time, but showed loss of weight, depression, vomiting, lowered temperature, and slow pulse, besides renal inflammation.

METEOROLOGICAL PORTENTS.

To the Editor of THE LANCET.

SIR,—Time was when meteorological portents influenced the world largely and the occurrence of eclipses or the presence of comets was assumed to be of the first interest in the affairs of the world. It is permitted to wonder whether the influence of these portents still remains. The tropical storm which visited London on Monday last fell on a date when certain world changes had been prognosticated to occur. First, a statement had been issued by a certain religious community that the Second Advent was due on July 11th; secondly, that date corresponds, or is believed to correspond, with some date foretold by the measurements of the Great Pyramid, and these measurements have been assumed to foretell great changes in the spiritual progress of the world; thirdly, July 11th was the date fixed for the opening of Joanna Southcott's box.

Obviously the information concerning the Second Advent was inaccurate; and as I am ignorant of pyramid lore and of what the revelations of Joanna promised, I cannot guess how far the promises have been followed by performances. But the contents of Joanna's box must have blown on her reputation as a religious seer, assuming that any shred of that reputation was remaining.

I should be greatly interested to learn if there has been noted any marked disturbance in the mental condition of patients either in our lunatic asylums, in our hospitals, or under private care, owing to the fact that on the date when vast and various events were anticipated by romantic persons the portent occurred of a sudden and furious storm. There is reason for thinking there may have been such cases.

I am, Sir, yours faithfully,

July 12th, 1927. METEOROLOGIST.

IN his annual report for the year 1926 Dr. F. J. Waldo, senior coroner for London, again remarks on the increase of deaths ascribed to anæsthetic ether. He suggests that an analyst's certificate of purity should accompany all ether sold for inducing narcosis. He points out the need for pure ether to be delivered to hospitals and anæsthetists in light-proof packings in order to prevent the formation of deleterious impurities; his impression is that the decomposition of ether under the influence of light is a point with which medical men are imperfectly acquainted. He repeats his recommendations of (1) compulsory notification to the coroner of all deaths under the influence of an anæsthetic wherever they occur, and (2) the nomination by the Home Office of a small research committee of experts to coöperate with coroners in inquiries regarding death under the influence of an anæsthetic.

CIRCULATION CONSIDERABLY OVER TWO MILLION COPIES PER WEEK

A CAMPAIGN IN ITSELF

An Address
ON THE
STRATEGIC FRONT OF MEDICINE TO-DAY.

eing the Presidential Address delivered at the Annual Meeting of the British Medical Association at Edinburgh, on Tuesday, July 19th,

Y SIR ROBERT PHILIP, M.D., F.R.C.P. EDIN., LL.D., HON. F.R.C.S. EDIN.,
NORARY PHYSICIAN TO HIS MAJESTY IN SCOTLAND; PHYSICIAN CONSULTANT, ROYAL INFIRMARY, EDINBURGH.

[THE lecturer first briefly surveyed the three evious occasions on which the British Medical Asso ation had come to Edinburgh, calling attention to e links which connected Sir Charles Hastings with e city. He followed with an eloquent summary of ster's work and character, and continued :—]

If Listerism embodied the fruitful protest of a aster mind before the hecatombs which desecrated rgical practice in his time, Listerism did not stand one. Other influences were at work making for the tterment of national health. Lister was a mighty oneer. He was at the same time the expression his age. Side by side with the development of the volution in surgery there were indications of the ming wave of preventive medicine which, reinforced Listerism, was destined to advance with the tainty of a tide.

GRIM FEATURES OF COMMUNAL LIFE.

In the first half of the nineteenth century health nditions throughout the country afford in the wider nere striking parallel to the grim condition of spitalism which Lister found himself up against. Many pictures might be drawn from town and ntry. The state of matters in the metropolitan a about the time of Queen Victoria's accession y be described in the words of Dr. Southwood ith, physician to the London Fever Hospital, iting of the year which ended March 20th, 1838, l of the districts inhabited by the poorer classes, says: "Such is the filthy, close, and crowded te of the houses, and the poisonous condition of localities in which the greater part of the houses situated, from the total want of drainage, and the sses of putrefying matters of all sorts which are wed to remain and accumulate indefinitely, that, ing the last year, in several of the parishes, both eving officers and medical men lost their lives in sequence of the brief stay in these places which y were obliged to make in the performance of their ies. Yet in these pestilential places the industrious r are obliged to take up their abode; they have no ice; they must live in what houses they can get rest the places where they find employment. By prudence or forethought on their part can they id the dreadful evils to which they are thus osed. No returns can show the amount of suffering ch they have had to endure from causes of this l during the last year; but the present returns cate some of the final results of that suffering; y show that, out of 77,000 persons, 14,000 have n attacked with fever, one-fifth part of the whole; that, out of the 14,000 attacked, nearly 1300 e died. . . . It is notorious that this disease has n very prevalent during the last year among the istrious classes who have never received parochial f, and that it has found its way even into the llings of the rich, where it has proved extremely tal. Generated in Bethnal Green, in Whitechapel, St. George-the-Martyr, in Lambeth, in Holborn, it has spread to the better streets in the immediate hbourhood of these and similar places, and thence still wider and more airy streets at a greater ance, and ultimately to the most remote streets the great squares."

CHADWICK'S RECONNAISSANCE.

It was amid such surroundings that the sanitary conscience was awakened within the breast of Edwin Chadwick, who stands related to the development of public health somewhat as Lister is to the renaissance of surgery. To Chadwick's healthy, sane mind the world seemed a "lazar-house, wherein were laid numbers of all diseased." Environmental conditions made healthy life impossible. There was no escape, save by re-orientation and reform. Queen Victoria had just been crowned, Lister was 10 years of age, and Chadwick 37. Yet Britain was apparently spending little more than £2000 per annum towards everything that concerned public health.

Thence onwards, throughout a long life, Chadwick's thought and energy were constantly directed towards the recovery of the nation from the inevitable consequences of blindness and inaction. His secret "lay in the conception that the life of man is so entirely influenced and affected by its surroundings, that by a perfected sanitary code the death-rates may be made, practically, whatever we like to make them, until we arrive at that natural duration of human existence which is bounded by anatomical or physiological law."

Impelled by such considerations Chadwick began his insistent inquiries into the condition of London and the health of the labouring classes of other parts of England and Wales, which led to the appointment of the Sanitary Commission in 1844, and the formation in 1848 of the short-lived first Board of Health, of which Chadwick was one of four commissioners. Thereafter his labours—in chief part unofficial—were unceasing in relation to every aspect of sanitation in Britain and elsewhere. He was recognised widely outside Britain as one of the great master spirits, one of the first to awaken the careless public all over the world to the dangers they were creating for themselves. In France, towards the end of his life, he was described as "une des gloires de l'Angleterre."

Even if temperamentally he was not of the kind who drew all men unto him, Chadwick did not stand alone. He had close colleagues and keen fellow workers. Among these may be named especially Dr. Southwood Smith, Dr. Kay, and two men having special connexions with Edinburgh—namely, Dr. Neil Arnott and Prof. W. P. Allison, who occupied this chair at the 1858 meeting, and of laymen, Lord Shaftesbury, Charles Kingsley, and Florence Nightingale.

DAWN OF PREVENTIVE MEDICINE.

From 1840—when, thanks to William Farr, our system of registration began to have value—up to 1870, the death-rate of England remained uniformly high—over 22 per 1000 of the population. In 1869 the Royal Sanitary Commission was appointed "to inquire into and report upon the operation of the various laws then in force for promoting the public health and preventing epidemic diseases; and into and upon the administration of those laws, including the constitution of the administrative authorities, central and local, and the formation of areas proper to be controlled by local authorities; and into and upon the operation of the registration system in respect of certificates of causes of death; and the Commission was to suggest improvements in all or any of those matters, with the means for carrying such improvements into effect."

It is significant that the Royal Commission of 1869 followed the submission of a memorial to the Government by a joint committee appointed by the British Medical Association and the Social Science Association "to promote a better administration of the laws relating to registration, medico-legal inquiries, and the improvement of the public health."

REPORT OF ROYAL COMMISSION.

The Commissioners reported in 1871, and their recommendations, which have a remarkably fresh ring, included the following: "The present fragmen-

tary and confused sanitary legislation should be consolidated; the administration of sanitary law should be made uniform, universal, and imperative throughout the kingdom; all powers requisite for the health of towns and country should in every place be possessed by one responsible local authority, kept in action and assisted by a superior authority; there should be one local authority for all public health purposes in every place, so that no area should be without such an authority, or have more than one; the administration of the laws concerning the public health and the relief of the poor should be presided over by one minister . . . whose title should clearly signify that he has charge of both departments; the central authority . . . charged in one of its departments with the superintendence of all sanitary authorities, and equipped with a sufficient staff of officers . . . must nevertheless avoid taking to itself the actual work of local government; we would leave *direction* only in the central power. . . . The new department will have to keep all local authorities and their officers in the active exercise of their own legally imposed and responsible functions; to make itself acquainted with any default and to remedy it; it will have also to discharge to a much greater extent its present duties . . . namely, to direct inquiries, medical or otherwise, to give advice and new plans when required, to sanction some of the larger proceedings of the local authorities, to issue provisional orders subject to Parliamentary confirmation, to receive complaints and appeals, to issue medical regulations on emergencies, and to collect medical reports; every local authority should have at least one officer of health, being a legally qualified medical practitioner, or possessing such other qualification in medical science as shall be declared by the central authority to be satisfactory."

STATE ASSUMES RESPONSIBILITY.

The recommendations of the Commission were accepted in 1871 by Parliament. The Local Government Board—one for each division of Britain—was established. This constituted an initial step of first importance in the sphere of health. The State and Legislature now recognised as never before the meaning and value of the health of the people, assumed responsibility for its maintenance, and began to shape machinery on a national scale for its preservation and improvement.

The establishment of the Local Government Board, so far as it concerned health, implied (*a*) central guidance and direction, and (*b*) peripheral (local) interest and activity. It fell to the President of the Local Government Board, supported by eight ministerial colleagues and expert advisers, to consider matters affecting communal health and demands made by the quickened intelligence of the nation. Even if the Local Government Board seldom or never met, it devolved on the President to keep in close organic touch with 1809 local councils or boards which constituted the system. To those local bodies were assigned duties and responsibilities. Thus, the appointment by each sanitary area of a medical officer of health and a sanitary inspector was enjoined by statute. All this meant a very practical awakening throughout the land.

SANITAS SANITATUM, OMNIA SANITAS.

It was on April 3rd, 1872, at a great meeting in Manchester, in a speech which held "an enthusiastic audience with unflagging spirit for three hours and a quarter," that Disraeli recalled a suggestion he had made eight years before at Aylesbury—namely, that the words attributed to the wisest of mankind, "*Vanitas vanitatum, omnia vanitas*," must have been a misquotation, and that the words of the wise king were "*Sanitas sanitatum, omnia sanitas*," and that, if so, they constituted one of his best claims to be considered the wisest of mankind; and Disraeli concluded with the words, "After all, the first consideration of a Minister should be the health of the people."

1875–1927.

Thus far it has been my endeavour to show how, on the one hand, Lister was a forerunner in relation to preventive medicine, and how, on the other, his work reflected and re-enforced the trend of thought and effort of his time.

It may be convenient to recall some of the features of medical life round about the 1875 meeting, and compare them with the present day. A glance at the calendar of Edinburgh University for 1875 and at the record of the meeting is enlightening.

In 1875 the Medical Faculty of the University comprised 12 professors and 14 assistants, while the current (1927) list comprises 18 professors, 79 lecturers, and 38 assistants. At the 1875 meeting of the Association the separate sections numbered 6, while on the present occasion—after scrupulous pruning by the Arrangements Committee—they number 21. Reference to the titles of discussions and papers in 1875 emphasises the striking difference of outlook. The principles of preventive medicine, as understood to-day, were little in evidence. Of the numerous papers and subjects under discussion the only allusion to prevention occurs in connexion with scarlet fever, puerperal fever, and miscarriages. The relation of disease to micro-organismal life hardly emerges, apart from Lister's opening address. Bacteriology had not come into being. In 1875, for the first time, there was a section of public health, presided over by the Right Hon. Lyon Playfair, M.P. Yet it is to be observed that the subjects brought before the section included for the most part topics bearing on ventilation, drainage, vital statistics, the meteorological relationships of disease, &c., with little indication of the preventive outlook in the modern sense.

HAS THE PRACTICE OF MEDICINE ADVANCED SINCE HIPPOCRATES?

At the meeting in 1875 the address in medicine was delivered by one of the most thoughtful physicians of his age, Dr. James Warburton Begbie. He took for his subject "Ancient and Modern Practice of Medicine," and by way of preface quoted a remarkable question asked in 1852 by Sir William Hamilton, who was long the distinguished exponent of philosophy at Edinburgh: "Has the *practice* of medicine made a single step since Hippocrates?"

Sir William Hamilton's rather negative answer to the question was traversed by Dr. Warburton Begbie in an historical review which, even to-day, the student of medicine will find interesting, and by the citation of recent advances in treatment to which, at that date, Dr. Begbie thought reference was especially due. If the champion of medicine in 1875 was able to rebut effectually the reproach implied in the question, how much easier would be the task to-day? It is not my purpose to advance a studied defence. Progress in the practice of medicine during the past 50 years has been phenomenal. Countless illustrations will occur to everyone who is familiar with the developments of the past half century.

The great wave that was initiated by the genius of Pasteur and re-enforced by the originality of von Behring has refreshed the brain of medicine and directed its energies into channels of amazing width. Need I cite the complete revision of outlook and practice in the ever-widening group of infective processes? The adaptation of the principles of scientific cleanliness and the utilisation of the elemental properties of air and light, as notably in tuberculosis, have got deep down to the root of things, and give promise in the realm of medicine no less extensive than has been realised by the acceptance of Listerism in the realm of surgery. What more thrilling romance than the story of tropical diseases which, 50 years ago, constituted a *terra incognita* shrouded in mystery and tragedy? Recall the triumphs in relation to cholera, malaria, dysentery, enteric fever, sleeping sickness, and others. Incidentally, I may remind you that it was at the last meeting of the Association at Edinburgh in 1898 that Sir Patrick Manson revealed

to a thrilled audience the demonstration of the transmission of malaria by mosquitoes.

Recall the extending list of diseases which have been traced to intoxications and to parasites. The murky, malodorous fog which enveloped venereal disease has been largely dispelled. Syphilis and gonorrhœa are handled openly and scientifically throughout the land.

Recall the great vista opened up by clinical observations and experimental investigation on the ductless glands, which has resulted in a reconception of glandular values and the constitution of a new department of medicine—endocrinology. Recall our present attitude to the nervous system. While the teaching of the nervous system given to undergraduates 50 years ago covered the broad lines of structure, function, and pathological disturbance, the gap is indescribable between that and the precision of to-day, whereby lesions of very varying character can be differentiated and localised almost with the certainty of the physical laboratory. A department of neurology has been constituted, and the practice of psychiatry has become scientific. The old asylum as a house of detention with sombre portal (Abandon hope, all ye who enter here) has become transfigured by the spirit of the age into a home of prevention and a tabernacle of hope.

Diseases of the circulation were well understood 50 years ago. In no department had British medicine rendered more conspicuous service since the days of William Harvey. But think of the increase of knowledge and application of exact methods which the present generation has witnessed. The problem of the circulatory mechanism has been linked with that of the circulating fluid. The secret of blood changes as cause of disease and as expression of disease has been gradually unfolded by patient, original investigations. Cardiology and hæmatology now form departments of their own.

Similar references might be made to advances in relation to diseases of respiration, digestion, excretion. By the application to medicine of biological principles and chemical and physiological procedure, the physician is throwing light on the meaning of symptoms and changes previously obscure, and the department of biochemistry has emerged.

The natural history of diseases is being followed from the beginning, step by step, through successive stages which almost certainly develop unless the chain of events be broken by other influence. With what remarkable éclat this succession of events can be interrupted was dramatically illustrated in the discovery of insulin, which, whatever its ultimate place in the armamentarium of medicine, has effected changes in the life and outlook of a large group of human sufferers such as was hardly conceived possible a few years ago.

Other such therapeutic conquests occur to us all. I am little concerned for the moment with cataloguing their number. My purpose is rather to underline the statement that, within recent years, truly marvellous advances have occurred in the practice of medicine. These have been partly the natural development of lines of observation, long continued, at the bedside and in the post-mortem room. In considerable part they have resulted from the absorption into medicine of advances in the basal sciences of biology, physics, chemistry, anatomy, and physiology.

Those illustrations have been culled at random from the field of medicine, in view of Hamilton's question. Examples might have been found no less abundantly in relation to surgery. The point has already been developed in speaking of Lord Lister. Anæsthesia and asepsis paved the way for a sure and rapid development of surgical procedure. Technique became quickly refined and surgery bounded ahead. With the limitless opportunities tragically offered by the war and the urgency of peril which justified the knife as never before, there came the occasion of enterprise to many capable men who otherwise would not have had the chance. Whether the spirit of adventure has carried some of them too far, it is not my present purpose to consider.

Most of the so-called specialties have reared their heads since 1875. Many have become lusty growths, scientifically based, beneficent to the sufferer, and not unkindly to the labourer who is worthy of his hire. If the critic speak lightly of the specialist, it is often through ignorance of what specialisation in the proper sense means, and the scientific advances it implies. In his turn the specialist will be watchful, lest limitation of the scientific spirit and the presence of other motives give point to the captiousness of the cynic who, ignorant of the verities, is apt to interpret action according to his own standard.

EXTENSION OF FRONT LINE.

It is to more general indications of change that I now ask your attention. From the side of the State, following the creation of local government boards, came the gradual development of machinery, both central and peripheral. This was a difficult and delicate matter. The necessary adjustments at both ends required time and patience. Yet, as Sir John Simon says, "the fact that the medical profession had been brought into statutory relations with the local government of the kingdom, even though the relations were yet of rude kind, was obviously in principle a fact of good sanitary promise. . . . The medical profession being of such spirit as it happily is, those who knew it could feel sure that by many of its members who had become officers of health under conditions most disadvantageous and discouraging, great exertions would be made, great disinterestedness be shown, in trying to make their individual appointments bear fruit."

An obvious difficulty lay in the fact that local authorities were not all willing to do their part, and, even when they were willing, their knowledge and vision were limited. Time and education were required. It is impossible on the present occasion to follow closely the stages in the evolution of the boards' activities, which included not merely administration, but scientific inquiry and investigation. We must look rather at the outcome of these developments.

The passing of successive Public Health Acts, the National Health Insurance Act, and the Education Act, have stereotyped progressive advances and afforded fresh avenues of thought and effort.

Outward symbols of change are to be found in notification of certain infections, the segregation of fevers and other cases in special hospitals under expert direction, the creation of bodies of medical officers concerned with tuberculosis, maternity and child welfare, venereal diseases, inspection of school children, &c. Other evidence is yielded in the institution by the universities and licensing bodies of degrees and diplomas in public health, and, in connexion therewith, a special curriculum of training recently revised and extended by the General Medical Council. In Edinburgh University, for example, there was established in 1898 a chair in public health, and about the same time a special institute for the study of preventive medicine; also in 1898 a lectureship on diseases of tropical climates, in 1904 a lectureship on infective fevers, in 1913 a chair in bacteriology, in 1917 a chair in tuberculosis, and in 1919 a lectureship on venereal diseases, all of which have intimate relationships with the problems of prevention, immediate and ultimate. One of the latest outward expressions of the advancing tide is the munificent gift to the nation by the Rockefeller Foundation of £400,000, for the purpose of erecting the London School of Hygiene and Tropical Diseases.

On the eve of the last Edinburgh meeting (1898) it fell to me to publish in the *British Medical Journal* an address on the universal applicability of the open-air treatment of pulmonary tuberculosis. At that date there were not more than two or three sanatoriums in Great Britain. To-day there exist in England, Wales, and Scotland, under the control of the State, no fewer than 307 sanatoriums, excluding

general hospitals receiving cases of tuberculosis, and 151 voluntary or proprietary sanatoriums. At the date of last meeting there was one tuberculosis dispensary. To-day there are in England, Wales, and Scotland, under the direction of the State, 515 dispensaries, and similar institutions have been established in most countries of the world.

In 1875 the mortality from all forms of tuberculosis in Scotland was 361 per 100,000, while in 1925 it was 110. In 1875 the mortality from pulmonary tuberculosis in Scotland was 252 per 100,000, while in 1925 it was 76. In other words, during the 50 years there has occurred in each case a total drop in mortality of over two-thirds. This is something more than part expression of the reduction of the general death-rate of the country, in which the fall during the same period amounted to less than one-half. The relative fall is illustrated by the fact that, while in 1875 deaths from pulmonary tuberculosis constituted 10·6 per cent. of deaths from all causes, in 1925 they constituted only 5·7 per cent.

If, in England, Wales, and Scotland the death-rate of 1875 had continued, there might have been expected in 1925, with the increased population, 107,999 deaths, whereas actually only 36,116 deaths occurred. In other words, there was a saving of 71,883 lives during the year—that is, over 66·5 per cent.

Having regard to the natural history of the disease and the possibilities of well-concerted warfare, I ventured in 1910 to prophesy, when speaking of the adoption in New York State of a coördinated tuberculosis scheme like that adopted by Britain three years later, that, granted the serious prosecution of the scheme, and special attention to the child as potential tuberculosis seedling, the practical disappearance of tuberculosis might be expected by 1950–55. To-day, in spite of the interruption and difficulties introduced by the war, I am prepared, on the necessary assumption that the methods are vigorously pressed, to believe that my successor at the next Edinburgh meeting—say, 30 years hence—will speak of tuberculosis in this country as largely a memory of the past.

By the passage of the Act which established the Ministry of Health (England) and the Board of Health (Scotland) the State has even more definitely—if language implies anything—shouldered her responsibility in relation to preventive medicine. A beginning has been made towards the inclusion and coördination under a common head of administrative departments concerned with health matters. It is not my purpose to discuss the completeness of the provision or the sufficiency of details. There has been a good deal of stumbling and muddling which seems characteristic of progress in England, but the machine, even if cumbrous and creaking, is functioning throughout the land. I am content for the moment to underline what I believe to be unchallengeable, that Britain possesses the amplest machinery to be found anywhere for the prevention of disease—machinery which, by reason of its completeness from centre to periphery, and its uniformity of operation, is justly the envy of the world.

WIDENING OBJECTIVE.

If the present position is relatively good, it has been the outcome of continuous striving after ideals inspired in the earlier days by individual thinkers and workers. But we are far from the last lap in the race.

One thing is clear. Things will not rest where they are. What is to be the line of further advance? The man-power of medicine is vast—greater than ever. The field forces are distributed in instructed groups. They are well officered, and there is abundance of consultative and advisory bodies to whom debatable points may be referred. What is to be the objective of this mighty army? What is the strategic front of medicine to-day?

Medicine has been described as the science and art of healing. Throughout the ages she has been the champion of man against disease and death. Her sacred mission has been expressed variously in successive centuries. Her triumphs have been great.

It has been my endeavour to show that some 80 years ago there began to be evident a great turning movement. The vision of medicine became enlarged and the objective correspondingly altered. Without passing from the care of the individual sick man, for whom medicine will always have earnest solicitude, she has gradually begun to think in terms of groups and communities. In Britain this change of outlook has been hastened by the great wave of urbanisation which has passed over the country—a transfer within less than a century from 75 to 25 per cent. rural population, and from 25 to 75 per cent. urban population. This has inevitably directed thought towards common causal factors of disease—environmental influences which, significant as they are in the individual case, can be studied and interpreted best among the aggregations of men. This has insensibly determined inquiry towards the prevention of disease. This, in turn, has impelled consideration of the early manifestations of disease. Medicine has ceased to be merely the healing art.

COMMUNAL EFFORT: GROUP PRACTICE.

The fact of illness means much to the sick man, and has a first place in his doctor's mind. Yet from another point of view the treatment of the individual becomes an incident in a larger enterprise. Individual illness means more than it used to do. Its occurrence raises far-reaching questions of cause and of remedy the solution of which will lead to the prevention of similar occurrence in persons similarly disposed all over the country. Those considerations are of particular significance in relation to widely prevalent diseases such as cancer, tuberculosis, rheumatism, occupational disorders, &c. Such affections take time to develop. Yet for the most part they are well established before they come under review by the doctor. If medicine is to be effective in respect of these conditions, it can only be by an alteration in the attitude both of doctor and of patient.

The doctor is sometimes called the family adviser. To what extent is the relationship which that term connotes realised? To what extent is it realised in family practice? To what extent is it realised in group practice? The introduction of panel practice—whatever objection may be taken to the particular model established by the statute—has opened great possibilities. The panel doctor, retained as medical adviser, continues to treat illness and accident as before, but he has a potential in relation to persons on his panel which, if thoughtfully used, may make for prevention on a large scale. In view of the form of contract, it is indeed to the selfish interest of the doctor to consider and anticipate environmental conditions likely to prejudice his clientèle. It will be to the mutual advantage of patient and doctor that he should become a preventive agent; and the health of the community will be correspondingly advanced.

The principle is readily applicable in all group practice and might advantageously be extended to what is generally known as private practice. What is wanted is a scheme of intelligent protection against illness. Why should not private contracts be arranged on the oriental line of payment for keeping the client well? At least there should be between doctors and patients common agreement as to the advisability of periodic physical examination, on the lines of inspection for recruitment or life insurance, so that morbid tendencies or threatenings of disease may be nipped in the bud.

A number of years ago, when consulted by large employers of labour regarding the frequency of tuberculosis among their workers, it seemed to me right to advise them that "in the light of present day knowledge, the occurrence of tuberculous disease in a certain number of workers may be interpreted as in part at least, one of the penalties of industrial life. On economic no less than on scientific grounds the

is much to be said for the institution of a method which would insure that every newcomer to a given industry is, prior to admission, specially examined for the presence of tuberculosis—more especially pulmonary tuberculosis—and, if accepted, is thereafter examined from the same point of view, every four to six months, especially during the first few years." Such a scheme would assure advantage to the individual concerned, to his fellow-workmen, and to the employer alike. Some of the great insurance companies across the Atlantic have thought it worth while to arrange for the periodic examination of their policyholders. I have been assured by representatives of one company that from their point of view this is a good business proposition: Prevent serious illness and postpone death. Thereby maintain the annual income of the company through premiums and defer the ultimate payment to the policyholder, who is not likely to complain of the advantage which thus accrues to the company.

Why should such a system of medical examination not become general, and the family adviser be enabled to play his proper part in the prevention of disease? An approach to the method is already in vogue with the dentist, who enjoins his clients to submit to a periodic dental review, to which the client, with experience of pains and penalties, commonly accedes. If the owner of a valuable car thinks it sound economy to send it from time to time to be overhauled at the garage, why should expert overhauling of the human machinery seem less desirable?

Out-Flanking Movement.

The further disposition of the forces calls for a wider orientation of the field. The ultimate goal is something beyond mere prevention of disease, as commonly understood. The negative attitude is too restrictive. It is scientifically insufficient and unsatisfying. The final triumph of medicine will consist not in the exclusion of disease, but in the restoration to man of perfect form and natural function: the attainment of smooth activity of body, mind, and soul. Biology—anatomy and physiology—must be relied on to carry us further than pathology and therapeutics, as commonly understood. Medicine, thus enlarged, becomes a department of biology and constitutes, pro tanto, the science of human life.

Our pathological museums will then serve as agents of preventive medicine. I foresee a time when the bottled preparations—the "beautiful" specimens of to-day—will figure in large part as do ancient manuscripts in our libraries, or as the crude relics of the dark ages in an antiquarian museum. They will stereotype to all time some of the vicious by-products of partial civilisation—of imperfect adaptation to environment—and afford cogent stimulus towards revision. Further recurrence of the conditions they illustrate will come to be regarded as little short of criminal.

Unity of Purpose: Collaborative Effort.

If the larger objective is to be reached there must be unification of purpose and solidarity throughout the forces engaged on the long strategic front. This involves considerations as to the training of students of medicine, and of candidates qualifying for special diplomas and for the nursing profession. It involves the direction and scope of medical research. It involves questions regarding the utilisation and coördination of different grades of hospitals and other medical institutions. It involves the relationships of various groups of medical practitioners to one another, and the relationship of the general body of medicine to various departments of the public health service. It involves the mutual relations of medicine and the general public, and the methods for securing trust and compliance. It orients afresh the connexion of medicine with the State. It makes insistent call for international goodwill and coöperation.

[Sir Robert Philip here detailed the menacing records of recruiting statistics, saying that the teaching of biology is not sufficiently insisted upon, and that research is not sufficiently conducted upon right principles. He continued:—]

Reorientation of Medical Needs.

The provision of well-equipped hospitals for the sick is one of the satisfying aspects of our civilisation. At first their foundation was for the most part voluntary. The inspiration was humanitarian and Christian. And long may the inspiration continue! The good Samaritan was a voluntary worker, unofficial, neither levite nor pharisee. The immediate object of the hospital, like that of early medicine, was relief of the individual sufferer. This outlook largely continues.

Now that the nation has shouldered the wide responsibility of both treatment and prevention, a reorientation of medical provision is necessary. The supply of hospital beds for persons who are seriously sick and in need of skilled care must be adequate in extent and fair in distribution throughout the country. But if hospitals are to have effective value in the larger field of prevention, there must be developed fuller possibilities for scientific investigation, and a completer follow-up service in relation to individual patients and their environment. The significance of this last point was pressed by me conspicuously in relation to tuberculosis, and formed a main plank in the programme of the tuberculosis dispensary as originally conceived 40 years ago. As to its value when properly conducted, there cannot be two opinions. The difficulty lies in the coördination of effective agencies.

The natural agent in the follow up is the family doctor, whether private or panel practitioner. In proportion as he is able to develop the preventive outlook, things will go well. When such natural provision is absent, or insufficient, there falls to someone else the delicate task of projecting the benefit obtained in hospital throughout the life of the patient at home and at work. This has become the field of the almoner or health visitor. Satisfactory fulfilment of the mission calls for wisdom and prudence in high degree. Within the field there are rich opportunities for scientific and social investigation.

In addition to the extension of service rendered by the individual hospital, there is great need to link up and coördinate the various types of hospitals. The different elements in the hospital network must be more or less united—loyal to the common cause and to each other. The élite within the group must lay less stress on amour propre and more on esprit de corps: Noblesse oblige. The better equipped hospitals and medical schools might do much to help smaller institutions and the great body of practitioners by sending out members of the staffs to coöperate with, and keep up to date, men who are stationed in the periphery.

The attitude of the Central Health Authority to the hospital question should be: Give us assurance that an adequate number of beds is available for the needs of the country, and that these are justly distributed in respect of the various areas and the various groups of diseases, and that their links with each other and with ancillary services are sufficient; it matters not to us whether the hospitals are maintained by voluntary effort or by the rates, or by such other machinery as may be found serviceable to the end. The fundamental requirement is that the Central Health Authority should have guarantee from the local authority that the provision of beds is adequate to the needs of its area, and that a jealous outlook is maintained in the direction of prevention.

Unification of Command.

As a preliminary to this, it is essential that responsibilities and powers relating to everything that concerns national health be vested centrally in one supreme health authority in the several portions of the kingdom, and peripherally in the various local health authorities acting under the central authority towards the common end. This means the inclusion in the department of health of a number of activities

which are presently outwith the department. The exclusion hampers procedure and development. Thus, in respect of hospital accommodation, there is everything to be said for the transference to the health department of the responsibility for medical treatment and care which is presently exercised by Poor-law authorities. All hospitals for the treatment of the sick should be included as component parts of a more or less uniform system applicable throughout the country. The legend over the door of the Royal Infirmary of Edinburgh—Patet omnibus—must inspire the nation's policy in matters of health. The advantages that would accrue to such transfer and combination are obvious in respect of the output of the collective group of hospitals, whether we consider that in terms of the treatment of the sick, the training of students and nurses, or the advance of medicine by observation and research. Let us hope that within a very short time the rearrangement will be secured by Act of Parliament.

ECONOMIC ALIGNMENT.

In connexion with the provision of hospitals, it is to be borne in mind that, in proportion as the preventive attitude is assumed by the medical profession, unofficial as well as official, the need for certain classes of hospital will grow less. This will bring economic advantage. Thus, when the truth of the dictum comes to be adequately accepted that "the tuberculosis of a people begins in the nursery and school-room, and that it is to the nursery and school-room that observation and effort must be directed if measures for the eradication of tuberculosis are to be fundamentally sound and practically effective," the need for the provision of hospitals for advanced stages of visceral disease and for crippled frames will progressively diminish. The time will come when hospitals for advanced disease and settlements for tuberculous wrecks will be regarded as anachronisms. In proportion as it is recognised that tuberculosis may be prevented or, at least, that the worser consequence of infection may be anticipated and averted, the scheme of remedial institutions which are immediately necessary because of the ignorance and neglect of the past will undergo progressive modification and curtailment.

With widening vision regarding hospital and ancillary services the relation between different sections of the profession will become simpler. Attachment to hospital and other medical institutions will become more general in the medical ranks. The medical corps throughout the land—official and unofficial—will be welded by the common aim to conserve the health of the nation. The result of the effort will depend ultimately on the general practitioner. It is to the family doctor, who is the effective embodiment of the spirit of the profession, that the nation must look for the development of the turning movement towards health. The family doctor, to whom the home in all its health interests should be no less open than the sick room, can contribute most to complete the success of the new strategy. The resources of medicine must be pooled. If there be community of purpose and knowledge, the tactics of the new advance are not beyond the wit and power of the profession. It is up to each arm to do its part.

Eighty-seven years ago Charles Wilson, a Scottish country practitioner, summed up the results of his observations on the health of the labouring population of the border town of Kelso as follows:—

> "When man shall be brought to acknowledge (as truth must finally constrain him to acknowledge) that it is by his own hand, through his neglect of a few obvious rules, that the seeds of disease are most lavishly sown within his frame and diffused over communities; when he shall have required of medical science to occupy itself rather with the prevention of maladies than with their cure; when Governments shall be induced to consider the preservation of a nation's health an object as important as the promotion of its commerce or the maintenance of its conquests, we may hope then to see the approach of those times when, after a life spent almost without sickness, we shall close the term of an unharassed existence by a peaceful euthanasia."

Most remarkable words, you will agree with me, for the year of grace 1840.

INTELLIGENCE DEPARTMENT.

The ordinary citizen needs to be educated. He is even now clamouring for knowledge. The lesson of health should begin in the school. Having regard to the marvellous heritage of health to which most individuals fall heirs at birth, it seems incredible that no systematic attempt has been made to instruct the entrant into life regarding its preservation. We must press for the more general inclusion within ordinary school teaching of training in the principles of health—*not* instruction regarding disease or a system of hygiene. What we want to ensure is, that the growing individual has a working knowledge of the make-up of his own body and its functions, and can appreciate beauty of form and know when smooth activity is disturbed. He must get to understand the close dependence of health on environment. The recent appointment at one of our public schools of a doctor as headmaster is an interesting experiment in the forward direction which seems to me commendable. The result will be followed with interest. It remains to be seen how the doctor compares with the clergyman and with the scholar in charge of developing boys. With youth sensibly trained about the machine which is peculiarly his own, it may be anticipated that within a generation the attitude of the nation to health questions will be completely changed.

Meantime, existing ignorance and post-war restlessness must be faced. There is need of popular education in the wider sense, and the dissemination of sound knowledge regarding health and the factors which make for disease. It must be insistently urged that, *the causes of disease being withdrawn, health restored.*

To avoid the difficulties and pitfalls attendant on sporadic propaganda by individual members of the profession there should be an ordered attempt to use legitimate means to achieve the purpose. Medicine must roll out "the song seraphically free of taint, personality." Why should not the British Medical Association, through its network of branches, serve as chief voice? Within recent times the Council of the Association has been consulted by, and has been accorded entrée to the Ministry of Health regarding debatable subjects. Why should not each branch similarly form an accredited medium of communication with the corresponding local authority by means of reports on matters affecting the health of the area, and with the larger public by the press through authoritative contributions on questions of living interest? The press is a great educator: it is *university of the man in the street.* Medicine must court its alliance and contribute her best to aid its efforts.

[Sir Robert Philip concluded his address with an eloquent description of the international aims of medical workers.]

UNIVERSITY COLLEGE HOSPITAL.—Recently Princess Mary, Viscountess Lascelles, visited the Maternity Hospital at University College Hospital and made a complete tour of the wards. The pressure on the maternity wards is so great that mothers cannot, as a rule, be kept more than ten days. The hospital was built out of the Rockefeller gift, and a sum of £180,000 was needed for the endowment of beds, of which £170,000 has been subscribed.

ALDERSHOT HOSPITAL EXTENSION.—The Mayor of Aldershot has inaugurated a campaign to raise money for a new operating theatre, X ray room, extension of the men's ward, and additional staff quarters at the Aldershot Hospital. More accommodation is badly needed in the hospital, and it is felt that in a town the size of Aldershot there must be adequate equipment to deal with both accident and disease. The estimated cost of the provision, extension and equipment is £6100, and the committee have raised £2800. Towards the additional £3300 needed the Mayor has so far received promises totalling £2000.

An Address
ON
CLINICAL TRAINING IN
OBSTETRICS AND GYNÆCOLOGY.

Read in Opening a Discussion at the Obstetrical and Gynæcological Society, Glasgow.

BY JOHN S. FAIRBAIRN, B.M., B.CH. OXF., F.R.C.P. LOND., F.R.C.S. ENG.,
OBSTETRIC PHYSICIAN, ST. THOMAS'S HOSPITAL, LONDON.

THE chief object of this paper is to urge the importance of clinical training in these subjects being so arranged that the students whilst learning their science and practice should also be stimulated to acquire the preventive bent of mind. Preventive medicine will not be considered as a special branch of medicine, but as an attitude of mind that may be developed and fostered in all the clinical studies. Obstetrics and gynæcology, especially if combined with or followed immediately by training in pædiatrics, offer a particularly favourable opportunity in this regard, owing both to certain distinctive characteristics of the subjects and to the late stage in the curriculum at which they are taken. During his service as medical clinical clerk and surgical dresser, the student has been taught from the pathological side—from observation of diseased and injured—because clinical material in hospital is of this type and because it is easier to teach diagnosis to the beginner on cases of well-established disease with obvious physical signs. The alternative system of beginning from the physiological side would appear to be the more rational sequence of the earlier non-clinical studies, but the testing of samples of the ordinary population in order to discover those showing weakness or early disorder of the bodily functions would be difficult to organise under present conditions in hospitals. Certain branches of medicine are suited to serve as training grounds from the physiological rather than the pathological aspect, and among these branches midwifery stands out prominently, for the very reason that it is so largely concerned with the normal processes of reproduction and how to keep them normal. If, however, the most is to be made of the difference in method, and if the student is to be trained in a fresh atmosphere, special thought must be given to the planning of the course of study.

THE ORIGINAL SYSTEM FOLLOWED AT ST. THOMAS'S HOSPITAL.

To illustrate the application of these principles, and to give a concrete example of an attempt to put them into practice, I will sketch the evolution of the system as now organised and working in my own school of St. Thomas's Hospital.

The system I wish to describe dates from 1910, and came into being as the result of the recommendations of the General Medical Council based on the report of the John Williams Committee of 1906—a report that marks an epoch in the teaching of midwifery in this country, because it marks the beginning of the era when clinical training in midwifery was no longer to be picked up casually on an extern district, with no other supervision than that of an inexperienced house officer. The driving force in London came from the universities of Oxford and Cambridge, which adopted the General Medical Council's recommendations en bloc and left the medical schools to find a way of making provision to meet them. The London University and Conjoint Board adopted only such of them as were not inconvenient to the medical schools of London. St. Thomas's, having a relatively high proportion of students from the older universities, determined to open a maternity ward for their clinical instruction. A ward of 21 lying-in beds with its necessary adjuncts was opened, making, with the gynæcological ward of 29 beds, 50 beds in all. With the addition of the extern district, providing at that time about 1500 deliveries per annum, and the out-patient department for diseases of women, the hospital was able to provide a three months' whole-time service—i.e., without other clinical work—for all its students. The first six weeks were spent in residence and in midwifery work; for four of these weeks the student learnt his clinical midwifery in the hospital, and for the other two weeks he applied the experience so gained in the houses of the district patients. The remaining period of seven weeks was devoted to in- and out-patient clerking in the gynæcological department. When not required in the maternity ward spare time was occupied by attendance at the various gynæcological clinics.[1]

This was the first maternity ward in a general hospital with a medical school of a capacity sufficient for the training of all its students. The annual number of deliveries was about 600. Though now general in the London schools it was the first combined training in midwifery and gynæcology through which all students passed. The department was increased as time went on by the addition of prematernity and infant clinics (the latter as part of the follow-up department of the midwifery patients), the details of which I need not go into. The department had reached a sufficient degree of development to be noticed and given a detailed description by the medical officer to the Local Government Board in his report for 1913–14 (page xxxi.).

THE SYSTEM NOW IN USE.

The 15 years' experience of having students working full time for three months in an "obstetric atmosphere" was a great education to those responsible for their training. It made all of us realise the enormous value of "atmosphere." As time went on and the department expanded our ideas expanded also. The "preventive atmosphere" became more dominant, and on this account our department in the post-war years came into closer contact with the children's department. Although encouraged to attend, the students paid little heed to the clinics for well babies, for they had no examination value. The pædiatrician, however, held a clinic once a week in the maternity ward, which was attended both by the obstetric clerks and by the clerks from the children's department. The students who had passed through our department were encouraged to proceed immediately to act as clinical clerks in the children's department. The next step was to amalgamate the two departments and thus increase the length of time spent in the "preventive atmosphere," and also the strength of "prevention" in it. This amalgamation had been the obvious step for some years, and, indeed, was adumbrated by me in papers read at the discussions on Medical Education at the Edinburgh Pathological Club in 1918[2] and at the Obstetrical and Gynæcological Section of the Royal Society of Medicine of London,[3] but it was not until 1925 that our scheme was placed before our medical school council and accepted. Under the scheme each student gives six months' whole-time service to the combined study of obstetrics, gynæcology, and pædiatrics. It has now been working long enough for some impression of its advantages and possibilities to be obtained. Roughly the six months' service is divided equally between obstetrics, gynæcology, and pædiatrics. Residence in the hostel and within call is now extended to two months, during which the student's time is portioned out between the antenatal clinics (four sessions a week), the clinics for well babies (two sessions a week), the practice of the maternity ward and attendance on intern cases for the first month, and extern cases for the second month. Four to six obstetric clerks are on duty at a time and take their maternity cases in pairs,

[1] Brit. Med. Jour., 1912, ii., 1106.
[2] Edin. Med. Jour., November, 1918, xxi., 286.
[3] Proc. Roy. Soc. of Med., Sect. Obst. and Gyn., 1919, xii., 40.

but a general call to all students in residence is issued for abnormal cases in the maternity ward. The second two months is occupied by clerking and dressing in the gynæcological department and the final two months in the clinics for well and sick children, clerking in the children's medical ward, with attendance at gynæcological out-patients on two sessions a week.

The advantages obtained by this combination have been very striking to those who have been teaching from the earlier stages in the evolution of the scheme, and it may make them clearer to others if the contrast is pictured between the primitive stage when maternity cases, gynæcological practice, and attendance in the children's department were taken as isolated events in the curriculum, often sandwiched in between other clinical work, and the system as outlined above. If the total length of time given by the student to obstetrics, gynæcology, and pædiatrics is not increased by one day, and these subjects are but linked up into a continuous period of service so as to serve as an object lesson in preventive medicine, the gain is enormous. I predict that a comprehensive scheme for the clinical teaching of these subjects in chronological order, starting with the care of the pregnant and parturient woman and the maintenance of the health of the mother through reproductive life, and including the child through its early developmental stages, will, wherever adopted, be recognised as a great advance.

THE "PREVENTIVE ATMOSPHERE."

The next point I would make is that the student's outlook over the world of medicine may further be widened by coöperation between the various teachers in gynæcology and pædiatrics in the direction of developing a new and special "atmosphere" in which the teaching is conducted. Such "atmosphere" must naturally depend on the individual characteristics of the teachers and the school; its development may be fostered by careful arrangement of the curriculum. The subject of study is represented as the hygiene and care of the reproductive cycle, with the double objective of lessening the price paid by the mothers in bearing and rearing the next generation and of lessening death and disability among the new stock. So far as can be the teaching is from the physiological side, with the degree of the normal attained through pregnancy, labour, and lying-in and the early developmental stages of the infant as the criterion of successful practice. The care of the mother is made the centre-point, for she is the executive in the nurture of her family.

The differentia of this form of training becomes clear to the student when he discovers that the patients in the clinics—mothers and infants—are healthy and not sick folk, and that his object now is to maintain this state of health by seeking out the causes of disorder or early intelligence of its beginning. In time he acquires the habit of mind that leads him to review all abnormalities in order to see why failure of prevention has occurred. The student is also encouraged to think in terms of the community and of the importance of the subjects of study to the health of the nation. Many occasions arise of pointing out to him the evil results to the young family of ill-health in the mother, and of ignorance, carelessness, and lack of foresight in the parents. In the gynæcological ward he sees instances of the failure to prevent injuries and infections during reproduction with their ill-effects on mother and family. Thus he learns to look beyond the individual patient and visualise the results of bad midwifery, of bad hygiene, and neglect on both generations. Where there is a social service department, instruction on this side before beginning attendance on district cases widens the student's field of vision and adds greatly to his interest in and understanding of his patients. Many an obstetric clerk has told me that the talk from the lady almoner was the most instructive hour in his medical studies. The opportunity should not be allowed to slip of making this time of attendance on patients in their own homes a means of filling up the serious ga in a medical education that is otherwise based wholl on patients seen within hospital walls and divorce from the conditions of their everyday life.

THE TEACHING OF MIDWIFERY.

So far my argument has been restricted to th development of the preventive bent of mind in th student, and the obvious criticism may be mad that the paper so far has not yet touched on th actual teaching of midwifery. The equally obviou reply would be that midwifery is a branch of preven tive medicine, and no teaching in it can be adequat unless conducted in the atmosphere of preventio and so as to produce the essential mental attitude Is it not the lack of this attitude of mind that is th greatest failing of present-day midwifery? Th need for it is being preached everywhere, and thi paper is but a plea for its more intensive introductio into the training of the new entrants into the pro fession. We must get back to the primary aim o maintaining the natural processes throughout repro duction, and look on all interference with norma function or substitution for it as failure to secur our chief objective. Sound foundations for practic can only be laid in an atmosphere of preventio and there is no fear of the atmosphere being made s thick that the primary duty of doing the best fo the patient will not be clearly visible.

In teaching the practice of obstetrics and gynæco logy the chief difficulty that faces the teacher is tha of giving the student direct clinical experience o various complications of labour and obstetric manipu lative procedures and of bimanual examination o sufficiently large numbers of patients with norma and abnormal pelvic organs.

The antenatal clinic with its fequent attendance of women in all stages of pregnancy affords almos unlimited opportunity for acquiring skill in abdomin diagnosis and external manipulation and of learnin the supervision of pregnancy. I do not lay an stress on the desirability of the senior members of th staff teaching the management of normal labou My personal opinion is that no one can do it bett than a highly trained labour-room sister. The dut of the medical staff is to maintain a technique of hig standard so that the student, after spending a mont under its influence and witnessing and conductin labours as carried out according to the ordina practice of the labour-room, will acquire a hab that he will carry with him through his future practic For the abnormal cases, on the other hand, the co stant presence of an experienced member of the sta is necessary, and that is undoubtedly a weak sp in our teaching. It will be generally accepted th the principle of a chef de clinique living in t hospital—such, for instance, as the Master of t Rotunda—is the most satisfactory system for lar institutions, but few obstetrical and gynæcologic departments of a general hospital can provide t material to justify such a policy. An experienc resident chief for large maternity hospitals (especial if amalgamated with the hospitals for women) is t ideal for the training of students. This arrangeme was advocated by the Committee of the Obstetric and Gynæcological Section of the Royal Society Medicine in London that went into the question 1919.[4] That committee, regarding the matter fro the point of view of teaching, was strongly of opini that the move of the London medical schools to fo self-contained departments was a retrograde st and that the Rotunda plan of a large combin maternity and gynæcological hospital with experienced resident master and assistants was t best. The one thing in favour of the small unit with the large general hospital is that the resourc both in personnel and material, of the general hospi become available. I have served in a special matern hospital and on a general hospital with a matern ward, and have found the enormous advantages of t

[4] Proc. Roy. Soc. of Med., Sect. Obst. and Gyn., 1919, xii., 1.

laboratories with their skilled officers, the experienced personnel in all departments, and the additional resources for diagnosis and treatment that the general hospital affords and the special cannot provide.

The teaching of obstetrical manipulations must be largely carried out on the model, but should be kept in close relation with clinical midwifery—e.g., immediately after practice in the ward and on the district. The object of the teacher is to use the procedures the student has actually witnessed as the foundation and to build on them both the details of those manipulations he has seen and the whole procedure in those he has not seen.

The proper supervision of the student while attending labours and visiting patients on the district presents a somewhat difficult problem because someone more experienced than a temporary house officer is required. This duty should be assigned to an officer at least of the standing of a registrar or tutor and holding the post for two or three years.

The removal of acute puerperal infections and venereal infections from the immediate purview of the student makes it necessary to arrange special clinics elsewhere. These occasional visits help to fill in blanks in the student's experience, but cases demonstrated never make the same impression as those continuously under the observation of the clinical clerk. Constant thought is required to lessen the disadvantages of the specialisation and segregration both of methods of investigation and of cases by which they tend to be removed from the immediate observation of the student.

THE TEACHING OF GYNÆCOLOGY.

Gynæcology also has problems of its own. The material in hospital wards is far too largely made up of women admitted for operative treatment, and is in no way representative of the gynæcology of family practice. Diagnosis, both by abdominal and bimanual examination, can, however, be most readily acquired in the wards; the all-important point is that the out-patient department should be used to its fullest extent for teaching minor gynæcology and that a selection of minor cases for indoor treatment should be made. Gynæcology has to be taught almost wholly from the pathological side. Even we teachers suffer from lack of opportunity of examining the pelvic organs in women without signs or symptoms of disorder, and thus form an incorrect perspective. Attention must be concentrated on all injuries and diseases arising out of the exercise of the reproductive function and their causation and prophylaxis discussed fully, as well as the measures to be taken for their care or relief.

Neither the physiology of the reproductive processes nor the pathology of the reproductive tract receives such attention in the students' previous studies, and the opportunity should be taken to give this instruction during the time of service in the department. The more closely this teaching can be kept to the patients under observation the better. All pathological material should be demonstrated, naked eye and microscopic, as part of the clinical case and discussed from its clinical as well as its scientific aspects. In these demonstrations opportunity readily offers to show other and related conditions, so as to fill in what the student may not have seen clinically. Also normal material from abortions, placenta, &c., and the histology of the normal pelvic structures may be conveniently studied in comparison with morbid conditions.

THE ASSOCIATION OF OBSTETRICS WITH PÆDIATRICS.

A word or two may be said regarding the association of obstetrics with pædiatrics. The latter term has been used as connoting the study of the developing child from the physiological side, and pædiatrician or pædiatrist is adopted rather than "physician for the diseases of children" because it suggests the hygiene and management of the normal infant and prophylaxis as his primary study rather than the cure of the disorders and diseases of childhood. By bringing pædiatrics into close association with obstetrics, the area known to the public as "maternity and child welfare" is covered and provides a very sound apprenticeship for the student. Both are begun from the standpoint of physiology and have similar characteristics. Close coöperation with the pædiatrician is required, for the two subjects run together at times. The management of the mother, for instance, in all cases of difficulty with breast-feeding is reckoned as a problem in pædiatrics and not obstetrics. The much greater readiness with which the student takes to the study of the infant when it comes to him directly as part of the follow-up of his maternity work and as part of a scheme of preventive medicine has struck both obstetric and pædiatric teachers.

CONCLUSION.

My final point is to urge that if these subjects are combined into a consecutive study, and the benefit to the education of the student is set out in some such a way as I have attempted, a better case can be made for the granting of the necessary time or facilities. Midwifery is always described as playing Cinderella in the curriculum to her older and bigger sisters, medicine and surgery. For this neglect those professing midwifery are not altogether without blame, for they have not been very successful in playing the part of fairy godmother so as to display her charms and trick her out to be attractive. My experience in agitating for better facilities for clinical training and a larger share of the student's time has been that the more these wider aspects are stressed, and the more our teaching is described as that of the care of the reproductive cycle, of the mothers and of the rising generation, the stronger the appeal to our colleagues, lay or medical.

JAUNDICE IN RELATION TO SURGERY.

BY E. R. FLINT, F.R.C.S. ENG.,
ASSISTANT SURGEON, GENERAL INFIRMARY, LEEDS.

JAUNDICE is the term applied to the pigmentation of the tissues—clinically of the skin and conjunctivæ—caused by bile-pigment in the blood. The urine and fæces will show the presence or absence of bile according to the cause of the jaundice. The pigment is normally present in the blood in small quantities, a considerable excess (probably ten times the normal) being required before clinical jaundice appears; but before this limit is reached there is a condition of latent jaundice, cholæmia, which probably has considerable clinical significance.

The Formation of Bile-pigment.

The theory of the formation of bile-pigment is as follows:

Hæmoglobin is broken up into its two components, protein and hæmatin; the hæmatin undergoes a further change into an iron-containing moiety and an iron-free moiety hæmatoidin. The latter is nearly or quite identical with the bile-pigment bilirubin, and it is probably the source of this substance under normal conditions. It used to be held that the liver was essential for these changes, but Whipple and Hooper, and later Mann and others, have shown that bilirubin can be produced apart from the liver, and it is now generally believed that bile-pigment is formed by the reticulo-endothelial tissue of the body—a large part of which is situated in the spleen, bone-marrow, and liver—in the latter under the name of Kupffer's cells. That bilirubin can be formed by other organs than the liver receives additional evidence in hæmolytic jaundice, where removal of the spleen causes an immediate disappearance of the jaundice. The fate of bilirubin, once it is formed, is said to be this: It is passed through the polygonal cells of the liver and appears in the bile, probably changed in some way, and so into the intestine. Somewhere in the intestine it is reduced to urobilin by bacterial action, and this substance is reabsorbed in part and returned to the liver, where it is resynthesised into hæmoglobin by uniting with the iron-containing moiety which has been stored for this purpose.

Another view is that urobilin is formed in the liver; Whipple says there is no evidence of absorption of urobilin from the intestine. The urobilin unites in the liver with the iron-containing moiety to form hæmoglobin. Some of the bilirubin, of course, passes on into the bile. In support of this view the phenomena observed in hepatic cirrhosis are cited. Here there is excess of urobilin and urobilinogen in the urine, and it is held that the deficient liver function prevents the formation of hæmoglobin in the manner stated above. Urobilin passes on, then, into the hepatic veins and is excreted by the kidneys; as it does not take its full part in the forming of hæmoglobin, anæmia results.

Causes of Jaundice.

McNee states jaundice may arise for the following reasons:—

1. Bile-pigment, formed in the cells of the reticulo-endothelial system, passes through the polygonal cells normally to reach the bile capillaries, but is obstructed there and finally reabsorbed into the blood.
2. Owing to damage to the polygonal cells of the liver, the bile-pigment carried to them by the endothelial cells is unable to enter them. The bile-pigment would, therefore, pass directly along the hepatic venous radicles into the general circulation. On the other hand, part of the bilirubin might pass through, and part be unable to do so.
3. In excessive blood destruction too much bilirubin is formed in the reticulo-endothelial tissue for the polygonal cells to deal with. In such circumstances some pigment might pass normally into the bile capillaries and colour the fæces, while the excess might pass straight through the hepatic veins into the general circulation and bring about jaundice.
4. In addition to damage and disordered function of the polygonal cells, there is obstruction in the bile-ducts—for example, cholangitis. In such circumstances some pigment might pass directly into the hepatic veins and so into the general circulation, and some through the polygonal cells, to be afterwards reabsorbed on account of the obstruction.

Clinical Classification of Jaundice.

McNee classifies clinical jaundice into three groups: (1) Obstructive hepatic jaundice; (2) toxic and infective hepatic jaundice; (3) hæmolytic jaundice.

Van den Bergh's test has been of great help in elucidating problems connected with jaundice. When jaundice is due purely to complete obstruction of the bile-ducts the direct reaction appears with this test. When jaundice is due entirely to the hæmolytic type van den Bergh's test gives an indirect reaction. Therefore, between these two the test gives a definite method of distinction. But when the jaundice is due to incomplete obstruction, and in the toxic and infective forms, a biphasic reaction is seen, which probably indicates a combination of the first two types of jaundice in varying degrees, and therefore yields no definite information from a diagnostic point of view. Moreover, this mixed type of jaundice is the most common variety. Van den Bergh's test brings out some other interesting points; it shows clearly that there is a condition of latent jaundice, that is to say, there is excess of bile-pigment in the blood, but no clinical sign of jaundice. This occurs in cirrhosis of the liver, and so the test gives valuable help in surgical considerations of the gall-bladder and bile-ducts, for it is now beginning to be recognised that hepatitis, of more or less severity, is often present with gall-stones, &c. Again, in hæmolytic jaundice there is often a degree of cholæmia much above that which the kidneys would allow if it were due to biliary obstruction, which suggests that in the latter type there is something irritating to the kidneys lowering the threshold; indeed, in obstructive jaundice it is not uncommon to find albuminuria, and it is quite possible that the bile-salts are the irritating agents, as, of course, these do not get through into the blood in hæmolytic jaundice. Van den Bergh's test shows that bilirubin is increased in the blood in pernicious anæmia, but not to such an extent that the threshold value of the kidney for bile-pigment is reached, and biliuria results. In secondary anæmias, on the other hand—for example in malignant disease—there is no increase of bile-pigment in the blood.

Besides the different reactions to van den Bergh's test given by the sera in mechanical biliary obstruction and in hæmolytic jaundice cases, there are many clinical differences, which can be readily seen in the following table:—

—	Obstructive jaundice.	Hæmolytic jaundice.
Pruritus	Present.	Absent.
Urine	Bile stained.	Bile absent.
Fæces	Pale	Normal.
Bile-salts in blood..	Present.	Absent.
Pulse	Usually much slowed.	About normal; fast during crises.
Spleen	Not palpable.	Usually much enlarged.
Wasting	Rapid.	Weight maintained.
Red blood corpuscles	Increased resistance.	Increased fragility.

Some of these differences are undoubtedly due t the passing of large quantities of bile-salts into th blood. The bile acids are a combination of choli acid and amino-acid, of which there are two—glycin and taurin. Glycocholic acid is the one found i largest quantity in human bile. The bile acids occu in bile as sodium salts soluble in water. It is suggeste that cholic acid is formed from cholesterol, and tha a high cholesterol blood content is evidence of fault liver function in the formation of bile salts.

It is usually held that the slowing of the pulse i obstructive jaundice is due to the presence in the bloo of bile salts. I think there can be no doubt pruritu is also. This torturing symptom is only present i the obstructive type of jaundice, and then only in th earlier stages; with complete obstruction it is said th secretion of bile-salts ceases and pruritus passes o even while jaundice persists as deeply as ever. I ha noticed this over and over again in maligna obstruction of the bile-ducts.

Tests of Nitrogenous and Glycogenic Functions of the Liver.

Though Van den Bergh's test has given such interes ing information about bile formation, and provid great help in diagnosis, it does not tell us enou about the most important liver functions—viz., t nitrogenous and glycogenic, and from the point view of surgery it is essential we should have so knowledge of the liver in these capacities. Unfo tunately we have no absolutely infallible tests these functions, though there are two which gi information of some practical value; these are t dye test and the lævulose test.

Dye test.—After injecting phenoltetrachlorphthal intravenously, all but 3 per cent. is eliminated from t blood by the liver in 15 minutes or so; if the liver is diseas there is retention in proportion to the liver inefficiency.

Lævulose test.—This depends on the fact that when t liver is intact lævulose will not raise the blood-sugar c centration, whereas the ordinary sugars will; in patie suffering from definite lesions of the liver the lævul acts more or less like glucose, and causes a marked incre in blood-sugar concentration. As to the relation of t lævulose test to the degree of hepatitis often associa with gall-stone conditions, I am at present carrying out so investigations which I hope to publish later. The experime are not sufficiently advanced at the moment.

Before either of these tests give positive results th must be considerable changes, because probably o a part of the liver is called into action at any c moment, moreover the organ has an extraordina capacity for regeneration and hyperplasia on dema However, so long as this regeneration and hyperpla are sufficient to prevent any pronounced posit evidence of hepatic deficiency by the dye or lævul tests it is probably sound enough for surgical purpos

The de-aminisation of amino-acids is one of t important functions of the liver, and if it is not p forming this efficiently there will be a decrease in blo urea and an increase in the pre-urea bodies. Of cou in this respect the kidney function must be consider as deficient elimination of urea will ultimately ca an increased blood-urea even though the output fr

the liver is deficient. So far as the kidneys are concerned it may be said that if there is no increase of blood-urea, and the result of the urea concentration is satisfactory, the renal condition, in spite of the presence of albuminuria, casts, &c., does not contra-indicate operation.

Another important function of the liver is the detoxication of poisons and destruction of bacteria; of the efficiency of this function we have no laboratory measurement.

Value of Liver Tests to the Surgeon.

From the surgical point of view the van den Bergh test is of more use at present than any other. The patient's condition can usually be determined quite accurately enough for surgical purposes by clinical observations alone, but there are times when this test and the clinical manifestations do not agree, and this applies particularly to the condition of latent jaundice. In this there are no outward indications of jaundice, but the test shows high bilirubin values in the blood, though it is not established what degree of general hepatic insufficiency the defective bilirubin excretion indicates, there seems to be no doubt that in many cases of obstructive jaundice the polygonal cells are seriously damaged, so that a positive van den Bergh test may be regarded as giving presumptive evidence in latent jaundice of hepatic deficiency which is not manifest to ordinary clinical methods.

The importance of this revealed cholæmic state lies in the warning it gives as to the desirability, and occasionally the absolute necessity, for delaying operative procedures until certain measures have been taken to lessen the risks of operation, especially as regards postoperative hæmorrhage and hepatic failure. It is well known that patients with obstructive jaundice show an extraordinary propensity to capillary bleeding after operation. This is due to deficient calcium content of the blood. It is supposed that the toxic bile-pigment and salts are seized upon by the available calcium in order to reduce this toxicity, and so the calcium necessary to the process of coagulation is lost. Perhaps this is additional evidence of the change which bilirubin is supposed to undergo in passing through the liver cells, because this postoperative hæmorrhage is characteristic of obstructive cholæmia, although there is a great deal of bilirubin in the blood of the hæmolytic jaundice cases. The tendency to bleed may be due to some other cause than the bile-salts or pigment; anyway the indication is clear that more calcium is needed before operation; 10 per cent. calcium chloride in 5 c.cm. doses intravenously on three consecutive days will usually reduce the coagulation time to normal or thereabouts. One constant feature about these injections is the complaint by the patients that they experience at once an unpleasant feeling of heat all over the body. On several occasions I have taken the temperature whilst injecting the calcium and have found that, though normal before, it goes up during the sensation of heat to as much as 101° in some cases and rapidly comes back to normal. If the coagulation time still remains long after a course of calcium injections blood transfusion will often be found to reduce it temporarily—sufficiently long to enable operative procedures to be carried out successfully.

It is not uncommon to find a patient who has had a stone removed from the common duct, when there was no jaundice, react in a similar way as regards the tendency to bleed, as a jaundiced patient does. The van den Bergh test will show in these patients a state of cholæmia, and will be an indication for giving calcium before operation. The value of this preoperative preparation cannot be overstated. There is another practical point brought out by the van den Bergh test in jaundiced patients; it is possible to estimate whether the bile-pigment content of the blood is increasing or diminishing. If it is increasing the risks of operation are also increased, and there should be a postponement of the operation, if other considerations justify this; on the other hand, with decreasing values, operation may be performed with a risk little greater than when there is no jaundice at all.

Value of Glucose before Operation.

As regards hepatic deficiency, it has been shown that glucose has great value in protecting the liver cell from harmful agents, and as it is impossible to tell what is the precise state of these cells, glucose should be given as a routine. It may be given in unlimited quantities by mouth or in 5 per cent. solution by rectum, or in 3 per cent. solution in saline subcutaneously.

Glucose is not only used directly by the tissues, but it fulfils a very important function in maintaining the efficient combustion of fats. With insufficient glucose for this function the higher fatty acids do not undergo complete combustion and a state of acidosis develops. Constant vomiting and consequent starvation prevent an adequate supply of glucose, and the ill-effects are aggravated when the liver is not functioning properly. It may take weeks of careful treatment to bring these patients up to the state in which they can be considered reasonably fit for operation, and even then they will sometimes develop postoperative acidosis, especially after the use of chloroform. For this condition 10 per cent. glucose intravenously, controlled by insulin, sometimes works wonders. Chloroform should never be used. Whether chloroform produces its ill-effects directly on the liver, or on the tissues generally does not appear to be conclusively decided, but of its danger as an anæsthetic there is no doubt and especially when there is a pre-existing liability to acidosis. Gas, oxygen, and carbon dioxide is the ideal anæsthetic; and if anything more is required, as it usually is when stitching up the abdomen, the minimum of ether should be added.

Value of Water before Operation.

Another factor of the greatest importance before and after operation is water. Drabkin and Edwards have shown that in the hypoglycæmia due to insulin there is a shortage of water in the blood. Walters, Bolton, and Kligore have shown experimentally on dogs the value of water in preventing terminal renal insufficiency, which is very apt to occur along with hepatic deficiency. In their experiments not only did the urea progressively increase in the blood, but there was a fall in chlorides and an increase in alkalinity of the blood. When water and chlorides—especially water—were injected the blood-urea dropped.

Surgery in Various Forms of Jaundice.

For the type of jaundice which McNee in his classification includes under the heading toxic and infective jaundice surgery has as yet not been able to accomplish much. It cannot be relieved by operation on the distal side of the polygonal cells, but there is some hope that it may be in some early cases by tackling on the proximal side the focus from which the infecting agent is being delivered to the liver. In hæmolytic jaundice removal of the spleen gives beneficial results almost as good as in any other field of surgery.

With regard to obstructive jaundice the most helpful symptom in differential diagnosis is pain—real pain as distinguished from discomfort. Painful jaundice is virtually always due to stone; painless jaundice very seldom is, and in the former case the stone is almost always in the common duct; on the other hand, a stone in the common duct does not always give rise to clinical jaundice.

The surgical treatment of jaundice due to stone is the removal of the stone or stones and drainage of the common duct. As the gall-bladder is always diseased as well, it requires treatment, and in the presence of deep jaundice it is a surgical maxim, to which there are few exceptions, never to remove the gall-bladder, but to drain it and leave removal for another occasion. This is partly for the reason that cholecystectomy is accompanied by a much greater risk of postoperative hæmorrhage and partly because the rule should be to do the least that is compatible with efficient liver drainage in these

patients, who frequently have hepatic deficiency as well. The completely obstructed common duct will often be filled with "white bile"; this is a convenient term, but an inaccurate one, as the fluid contains neither bile-salts nor pigment, being the clear secretion from the cells lining the ducts. After inserting a tube in the common duct ordinary bile begins to flow again quickly as a rule; sometimes it fails to appear, and the patient dies. On other occasions normal coloured bile flows for a few days and then begins to get less and less pigmented, and the patient becomes progressively weaker, lethargic with a subnormal temperature, and usually vomits all that is taken by mouth. Jaundice does not as a rule deepen or appear if it was absent before. These patients always die in a few days as a result of this hepatic failure. Though it mostly happens after the relief of a complete obstruction, in much the same way as urinary secretion may fail after the removal of an obstructing prostate, yet I have seen patients fade out like this occasionally after cholecystectomy where there was no obstruction by stone in the common duct.

It is this kind of delayed biliary failure that preoperative treatment will do much to prevent, and the van den Bergh test will often prove useful in informing us of the threatening failure, and indicate the necessity for delaying operation until the patient has been brought into a safer condition.

As regards painless jaundice of the obstructive kind, the commonest causes are chronic pancreatitis, carcinoma of the pancreas, or more rarely of the bile-ducts, and pressure on the ducts from enlarged glands in the portal fissure. Nothing can be done for the latter. But undoubtedly for malignant disease which is causing a greatly distended common duct an anastomosis between the gall-bladder and the stomach or duodenum gives great relief. Pruritus, if present, disappears, though in my experience the stage in which itching is so troublesome is in the first few weeks, and frequently is passing away or has gone before the question of operation is put to the patient. Early operations in malignant obstruction of the common duct would save the patient much distress, for whilst pruritus exists it is a most torturing symptom. The liver is relieved of a great embarrassment after an anastomosis has been performed, the patient lives longer, and in greater comfort physically and mentally, for the disappearance of the jaundice leads him to believe that he has been cured of his complaint.

Chronic pancreatitis, when associated with jaundice, may be an instance of the painful or painless type. In the former case it is usually dependent on a stone in the ampulla, and the treatment is the same as that for stone without an accompanying pancreatitis. In the latter case, in the absence of any determinable cause—e.g., syphilis, arterio-sclerosis, &c.—it is usual to remove the gall-bladder on the assumption that this organ has infected the pancreas. The evidence of this is anything but conclusive; the gall-bladder may be greatly distended, which would be unlikely if it were in a state of chronic inflammation, and in these cases I believe the pancreas would recover whether the gall-bladder were removed or not. In view of the usual state of affairs—namely, that the liver is involved along with the pancreas, and the gall-bladder may or may not be—it is more reasonable to suppose they have all been infected from a common site, and that there is no reason, therefore, to remove the gall-bladder unless it shows unmistakable signs of disease. Prolonged drainage of the gall-bladder is not good surgery, in my opinion, for chronic pancreatitis; infection undoubtedly creeps in after this operation, and later the gall-bladder may have to be removed. The recurrence of symptoms after the biliary fistula has closed has been interpreted as a return of the pancreatic symptoms, whereas it is really due to the imposition of another complaint.

Jaundice coming on after operation, in the absence of an overlooked stone, is due to infection spread at the time of operation or to injury to the ducts. In either case it is painless. The ducts would never be injured if the surgeon took the trouble to see all the important structures before clamping anything. A tedious and often severe operation will be necessary to rectify the mistake.

Surgical Risks Run by a Jaundiced Patient.

It will be seen that the chief risks run by a jaundiced patient are hæmorrhage, hepatic and renal insufficiency, as well as those attached to unsuitable and improperly conducted operations. The clinical manifestations exhibited by the patient, together with the evidence furnished by the various tests, especially van den Bergh's, will enable the surgeon to gauge with considerable accuracy the physical state of his patient, and he can then improve it by the several pre-operative measures indicated. Good judgment, gentleness, and an accurate knowledge of what is being done during the operation will add to the safety of the patient, when the operation is conducted under the least dangerous anæsthetic. Operations on the bile-ducts are undoubtedly the most difficult of abdominal operations, and when the patient is deeply jaundiced they are the most risky; there is all the more reason, therefore, to do everything possible to reduce the risks. There is another danger—namely, pulmonary complications. In so far as these depend upon the renal and hepatic deficiency much has been done to eliminate them, but there appears to be other factors concerned, which at present we do not understand.

THE MORTALITY FROM HÆMATEMESIS.

AN ANALYSIS OF 526 CASES.

BY ERNEST BULMER, M.D., M.R.C.P. EDIN. AND LOND.,
ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM.

THE results of this investigation act as confirmatory evidence of the writer's previous experience; that is that hæmatemesis in general is a grave condition with a much higher mortality than is usually admitted, and that the optimistic prognosis often given in cases of bleeding gastric and duodenal ulcers is not borne out by the facts that have been collected.

A systematic search of the records of the medical side of the General Hospital, Birmingham, was made for all cases admitted on account of hæmatemesis of a severe nature, and in a period of 24½ years between the beginning of 1902 and the end of July, 1926, 526 cases were discovered. Out of the 67 fatal cases post-mortem records were available in 53 cases.

In the following table the cases are divided into their several groups:—

Disease.	Total cases.	Deaths.	Autopsies.
Acute ulcers	218	19	15
Chronic ulcers	249	29	23
Cirrhosis of liver	25	8	7
Cancer of stomach ..	7	6	4
Portal thrombosis ..	1	1	1
Melæna neonatorum ..	2	1	1
Doubtful cases	24	3	2

Acute Ulcers.

It was found very difficult to separate the acute gastric and the acute duodenal ulcers; using the presence of the pyloric syndrome as the criterion of the duodenal ulcer it was found that out of the 199 cases that recovered only two had a history of duodenal ulcer. In the fatal cases the task was simpler, and of the 15 on whom autopsies had been performed 13 were gastric ulcers, one was a pyloric ulcer, and one was a duodenal ulcer. Of the four fatal cases without a post-mortem examination two had histories suggesting duodenal ulcers.

Mortality in the Acute Ulcers.—Excluding one case in which death was due to perforation of the ulcer

into the lesser sac there remain 18 deaths out of a total of 218 patients; of the 71 males 12 died—a percentage of 16·9; of the 147 female cases 6 died—a percentage of 3·1. In the 19 fatal cases post-mortem examinations were performed in 15 with the following results:—

Death from hæmorrhage	12 cases.
" " septic parotitis and septicæmia ..	1 case.
" " perforation into the lesser sac ..	1 "
" " cerebral thrombosis and anæmia	1 "

The cause of death in the four fatal cases who did not have an autopsy performed was hæmorrhage in each; thus in the whole series 16 died of hæmorrhage, one from septicæmia and parotitis, and one from cerebral thrombosis due to anæmia. The remaining case died from another complication of the ulcer.

Site of the Ulcers.

Lesser curvature ..	10 cases.	Pylorus	1 case.
Greater " ..	1 case.	Duodenum	1 "
Cardia	1 "	Petechial hæmorrhages at fundus	1 "

Severity of the Bleeding.—In order to give some idea of the type of cases that have been included in this series, as they were all treated according to the accepted methods of the day, and after a careful consideration of the fatal cases it was found impossible to determine any departure from the routine methods in their case.

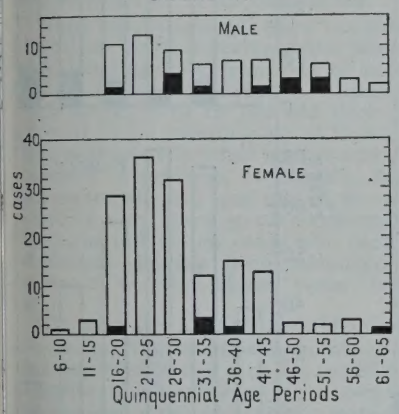
Chronic Ulcers.

The chronic ulcers will be dealt with under the same subdivisions as the acute ones in order that ease of comparison may be obtained.

Division into Gastric and Duodenal Ulcers.—Out of the 220 cases that recovered 14 had a history of duodenal ulcer, and of the 29 fatal cases in 23 an autopsy was performed—16 were gastric ulcers, five were pyloric ulcers, one was a duodenal ulcer, and in the remaining case there were coexisting gastric and duodenal ulcers. In the six fatal cases without autopsies the history of one suggested a duodenal ulcer.

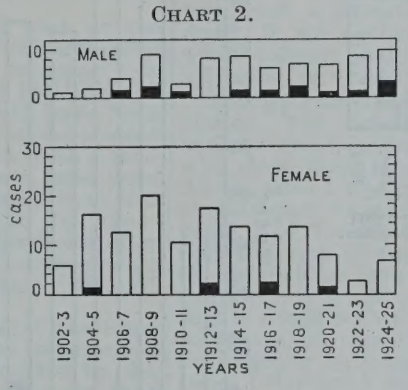
Mortality.—Out of a total of 249 cases there were 29 deaths—a percentage of 11·6; of the 89 males 15 died—a mortality of 16·8 per cent.; of the 160 females 14 died—a mortality of 8·7 per cent. In

CHART 1.



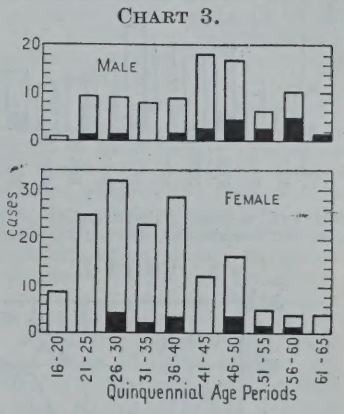
Age- and sex-incidence with the mortality in acute ulcers. (Deaths in black in Charts 1 to 6.)

CHART 2.



Sex and mortality distribution in two-yearly periods from 1902 to 1925. Acute ulcers.

CHART 3.



Age- and sex-incidence with the mortality in chronic ulcers.

analysis they have been divided into groups according to their severity, and it will be seen that the vast majority of the cases were admitted for a severe hæmatemesis. For the sake of convenience they have been further subdivided in this table into cases admitted in their first attack of hæmorrhage and those who had had previous attacks.

	First attack.	Recurrent attacks.
(*a*) Fatal cases	18 ..	1
(*b*) Very severe*	22 ..	2
(*c*) Severe	111 ..	18
(*d*) Moderately severe	18 ..	1

* Collapsed on admission.

The fatal cases were recruited, with one exception, from patients in their first attack.

Age- and Sex-incidence with the Mortality.—Chart 1 shows clearly the great difference in the age-incidence in the two sexes—the majority of the female cases occurred between the ages of 16 and 30 years, but the distribution of the male cases was fairly constant in the quinquennial periods between 16 and 55 years, with a slightly greater incidence, however, in the period of the highest female incidence. The greater mortality in the male cases is well shown.

Sex and Mortality Distribution in Two-Yearly Periods, 1902–1925.—It will be seen from Chart 2 that the female cases are on the whole tending to diminish in number, and that the deaths have been sporadic; the male cases, on the other hand, have tended to increase in number, and the mortality has been fairly constant, with a tendency to increase within the last two-yearly period.

Treatment.—It has not been considered necessary to enter into an analysis of the treatment of this

the 29 fatal cases autopsies were performed in 23 with the following results:—

Death from hæmorrhage	20 cases.
" " perforation into the portal vein and suppurative pyelophlebitis ..	1 case.
" " gastro-enterostomy done to check the bleeding	2 cases.

The cause of death in the six fatal cases who did not have an autopsy performed was hæmorrhage in five cases and terminal broncho-pneumonia in one case.

Site of the Ulcers.

Lesser curvature	16 cases.
Lesser curve and duodenum	1 case.
Duodenum	1 "
Pylorus	5 cases.

Severity of the Bleeding.—The cases have been classified according to the severity of the bleeding, but it was not considered necessary to divide them as to first attacks and recurrent attacks, as in the case of the acute ulcers. Out of the 29 fatal cases 7 had had severe hæmatemesis before the attack for which they were admitted.

(*a*) Fatal	29 cases.
(*b*) Very severe (collapsed on admission) ..	31 "
(*c*) Severe	148 "
(*d*) Moderately severe	41 "

Age- and Sex-incidence with the Mortality.—Chart 3 shows the difference in the age-incidence in the two sexes, but not to such an extent as occurs in the acute ulcers; there is a striking difference in the mortality, and the rise in the male death-rate at the later age-periods is well shown.

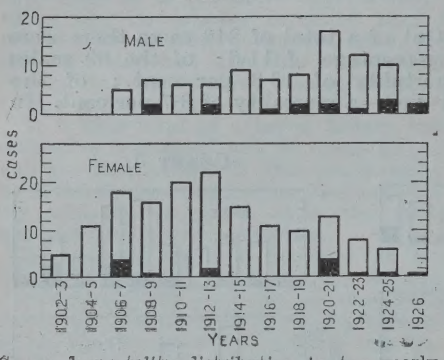
Sex and Mortality Distribution in Two-Yearly Periods, 1902–26.—Chart 4 shows very much what was brought out in the corresponding table for the acute ulcers—namely, that the female cases have

shown a tendency to decrease in number, while the male cases have displayed the opposite tendency, and their mortality has been greater in the later periods. In the incomplete year 1926 all the cases of chronic ulcer treated ended fatally.

Acute and Chronic Ulcers.

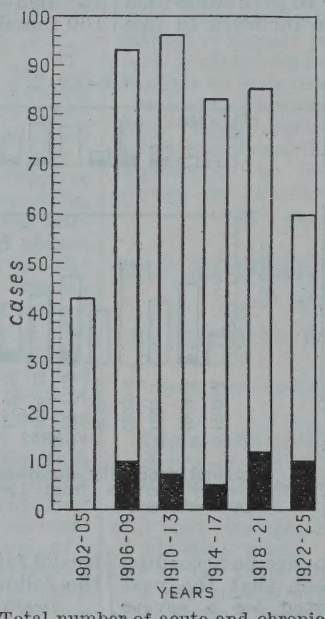
It is instructive to consider the acute and chronic ulcers together for some purposes. In Chart 5 the number of fatal cases and of total cases has been plotted together, and an increase in the mortality since the end of 1917 was discovered. Chart 6 shows the total number of acute and chronic ulcers divided into male and female cases with their respective mortalities over the same period, and in Chart 7 the total, the male and the female percentage mortalities have been plotted in order to show how the increased death-rate has been distributed. In all of these charts the number of cases has been reckoned over four-yearly periods.

CHART 4.



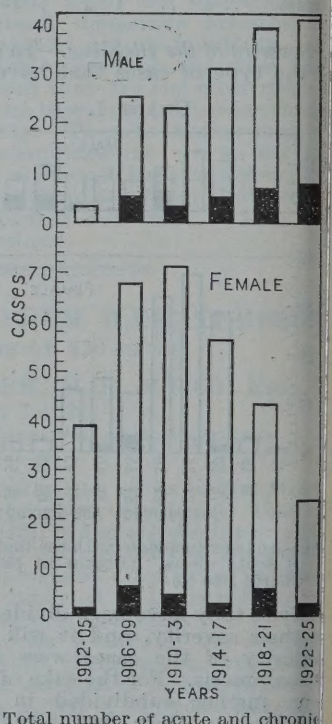
Sex and mortality distribution in two-yearly periods from 1902 to 1926 (July). Chronic ulcers.

CHART 5.



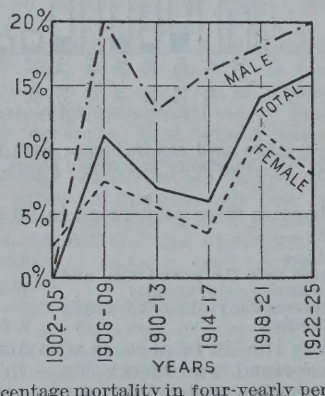
Total number of acute and chronic ulcers with the mortality in four-yearly periods from 1902 to 1925.

CHART 6.



Total number of acute and chronic ulcers divided into male and female cases in four-yearly periods from 1902 to 1905.

CHART 7.



Percentage mortality in four-yearly periods from 1902 to 1925. Total, male, and female.

Operations upon Acute and Chronic Ulcers.

The question of operations was considered under two headings, those performed as a method of treatment of the hæmatemesis, and those which were performed upon a patient who, at a later date, developed a hæmatemesis. The operative history of the series is set out below :—

(*a*) *Acute Ulcers.*—Two cases were operated upon ; in one this was done in convalescence and nothing was found except some adhesions between the duodenum and the gall-bladder. In the second case a gastro-enterostomy was performed with a Murphy's button as treatment for the bleeding, and the patient recovered.

(*b*) *Chronic Ulcers.*—In 12 cases who had had a gastro-enterostomy done for a gastric or duodenal ulcer some time previously a hæmatemesis occurred (not as a post-operative complication) and two of them died. At the autopsy the ulcers were found to be unhealed.

Five cases had had an appendicectomy done some time before, and one of them died of hæmatemesis.

Three cases had a gastro-enterostomy done as a method of treatment of the bleeding, and two of them died.

Three cases had a gastro-enterostomy done during convalescence.

Cirrhosis of the Liver.

Twenty-five cases of cirrhosis of the liver were admitted with profuse hæmatemesis and 8 of them died ; in 1 case there was no autopsy, and in the remaining 7 cases the source of bleeding was a ruptured œsophageal varix in 5, and it could not be found in the remaining 2 cases.

Cancer of the Stomach.

Out of seven cases admitted with profuse hæmatemesis six died and in four of them autopsies were performed. The causes of death were as follows :—

Eroded pancreatic vessel	2 cases
„ splenic artery	1 case.
Oozing from eroded splenic pulp	1 „

Portal Thrombosis.

The patient was admitted unconscious as an acute gastric ulcer, and died in a few hours. The post-mortem examination showed a portal thrombosis with no discoverable cause.

Doubtful Cases.

Twenty-four cases had to be included in this group :—

No case notes	10 cases
? Cirrhosis	3 „
? Carcinoma	3 „
No diagnosis was made	2 „
? Banti's disease	2 „
? Purpura hæmorrhagica	1 case.
Death from hæmatemesis with no post-mortem	1 „
Death from hæmatemesis in a case of renal infantilism—no source of bleeding at post-mortem	1 „
Death from hæmatemesis—post-mortem ? leukæmia	1 „

Melæna Neonatorum.

There were two cases of this condition, one was before the introduction of the modern treatment, and it died; the autopsy revealed no source of bleeding. The other was successfully treated by the intramuscular injection of the paternal blood.

Causes of the Increasing Mortality.

The causes of the increased mortality from acute and chronic ulcers are not at first sight obvious; Chart 7 shows that the total mortality has been rising since the end of 1917, but the rise has been better sustained among the male cases; the type of case has not altered materially during this period as it does not include the cases of hæmatemesis in young females of the type met with at the beginning of the century in association with chlorosis. The sex distribution of the cases has, however, altered in so far as the number of male cases with their higher mortality has risen and the number of the less fatal female cases has fallen. This will account to some extent for the rise in the total mortality, but the rise in the male mortality still remains to be accounted for.

Many explanations were considered such as the alteration in the severity of the cases reaching hospital with the improved methods of motor transport; it seemed to be a reasonable supposition that cases of such severity as in the old days would have been allowed to die comfortably at home are at the present time entrusted to a fast motor ambulance with a good prospect of arriving at hospital before a fatal issue has occurred. An analysis of the statistics from this point of view gave some confirmation to this hypothesis, as out of ten cases who died a few hours after admission—having been admitted unconscious—six occurred in the eight years between 1918 and 1925.

Whether any alteration in the method of treatment can be incriminated is a point of some importance, and one which will not be readily admitted by the majority of physicians. It is certain, however, that the amount of morphine given latterly has been greatly in excess of that used 20 years ago when a certain amount of caution in its use was advised. Morphine, as far as a study of the treatment sheets can be regarded as reliable testimony, was given at the outset to relieve pain, but the dose was small and not often repeated; the contrast with present-day methods is striking, and in no other method of treatment adopted has the change in usage been so noteworthy. The advisability of using morphine in large doses must, therefore, be questioned.

Summary.

1. An analysis of over 500 cases of severe hæmatemesis is presented with post-mortem reports upon 53 of the 67 fatal cases.

2. The mortality from acute gastric ulcer was 8·3 per cent.; in the males it was 16·0 per cent.; in the females it was 8·7 per cent.

3. The mortality in the chronic ulcers was 11·6 per cent.; in the males it was 16·8 per cent.; in the females it was 8·7 per cent.

4. The mortality from bleeding ulcers has risen during the last eight years, and some of the causes for this are discussed, with a plea for moderation in the use of morphine.

5. The cases of hæmatemesis other than in acute and chronic ulcers are tabulated, consisting of hepatic cirrhosis, carcinoma of the stomach, melæna neonatorum, portal thrombosis, &c.

6. Attention must be drawn to the fact that the mortality is much higher than the accepted one of 6 to 6 per cent.

In conclusion the writer must express his thanks to the members of the honorary medical staff of the General Hospital, Birmingham, for allowing him to publish the cases.

THE PREVENTION OF PYORRHŒA.

BY F. D. DONOVAN, L.D.S.R.C.S.,
SURGEON DENTIST TO THE ROYAL HOUSEHOLD.

THE cure of pyorrhœa has occupied the minds of most of the thinking dental and medical men during this last quarter of a century. The progression of the disease and the realisation of its possible consequences have led to much mental effort being bestowed upon it. The treatments are many, by quacks and scientists, hopeful and unhopeful, mostly expensive, and the cures are all doubtful. Efforts of the dentist, scaling, mouth-washing, home cleansing, and treatment in many cases do nothing but put off for a few years the inevitable result. Most dental practitioners have seen cases in early life, which they realise, if they are honest with themselves and their patients, must become before 40, cases of intractable pyorrhœa.

In acute stages much can be done to put off the inevitable extractions; but it is the slow chronic case, with apparently no cause, that resists all treatment, if we exclude the temporary improvement which follows local treatment, scaling, polishing and syringing, or a rise in the health index.

This pyorrhœa is universal and seems to attack all classes. The chronic cases are often more evident in those who take most care of their teeth—i.e., those who clean their mouths three or four times a day. At one time I was convinced that at the root of this chronic gum disease was the tooth powder or tooth paste, and I worked for some considerable time to find a source of common irritation which prepared the ground for future diseases. I looked for something which would so constantly irritate the mouth that it would reduce the membranes to a state of low resistance, so that the activating cause would have no difficulty in operating when it came along. At times I thought I was on the right track, only to find a series of patients who upset all my ideas and theories by having perfectly healthy mouths.

There is only one constant feature in all cases of chronic gum irritation. It is an article which is used by practically everybody in this country, and practically everybody amongst so-called western civilisation—I refer to the tooth-brush.

The Septic Tooth-Brush.

I am quite prepared to affirm that there is no tooth-brush, or there are very few tooth-brushes in the world to-day, that are not septic. I have examined very many, my own included. In point of fact I started with my own, taking a few bristles out and examining them bacteriologically myself. I was surprised to find my own tooth-brushes septic. Believing that the easiest person to carry out experiments on is oneself, I threw them away and bought some more. These were sterilised and examined, and found to be clean. They were then used in the ordinary way, with ordinary tooth-paste. They were washed, dipped in a mild mouth-wash, and put in the rack. Before the next tooth-brushing, some 12 hours later, they were examined again—still septic. This was repeated using different pastes and mouth-washes, &c. The brushes were also hung in the sun outside the window before being put in the so-called antiseptic cases supplied by the manufacturers. The result was invariably the same. I extended these examinations on many men living in the same club as myself. The net result was again the same.

My method of examination was to take, in the first place, a few bristles. If they were found to be septic that was quite enough. If they were clean, more were taken. I found that when examining the tooth-brush after 12 hours' rest—that is, before the second using—every bristle was septic. But when the tooth-brush was examined immediately after using, great bunches of bristles were found to be clean; so that I might safely say that immediately

after use the tooth-brush was slightly septic, but after 12 hours in the rack or case it was strongly septic. In reality, the infection was being incubated in the case for 12 hours.

Summary of Bacteriological Examinations.

Brushes examined, 500 ..	All these in common use. All septic in varying degrees.
„ „ 150 ..	Streptococcus isolated from 144.
Sterilised and examined, 40 ..	All clean.
Same brushes as above (40) examined immediately after use	Streptococcus found in few of the bristles in each brush. Many bristles quite clean. Patients were a mixed lot taken from ordinary practice.
Forty new brushes. Sterilised and used by same patients as above. The brushes were allowed to stand in rack after being used and washed in the ordinary way	All found to be septic in varying degrees. Streptococcus isolated from 37 of the 40.
Forty brushes used by same patients in the ordinary manner and immediately placed in some disinfectant (any ordinary one)	After 12 hours 36 were found to be clean, while four were slightly septic. Pyorrhœa alveolaris cases already.

Mechanism of Infection.

The infected tooth-brush is covered with what is, at the best, a mild antiseptic paste, and applied to the mouth. The infection from the mouth is incubated and then rubbed on the gums and spread over the mouth. Not content with this, scratches are made in the gums so that the infection takes even a better hold. With the average person this is done twice a day for a period extending over many years. It is started on the great day when baby first has a tooth-brush. It is common knowledge that while there are bacteria in the mouth they are to all intents on the surface of the body. Where scratches are made, infection is let in. The infection is encouraged, and at the age of 23 or 24 the gums are not what they should be. This fact is pointed out to the dentist, who polishes up the teeth, paints them with iodine, and tells the patient to use some mouthwash, and temporary improvement occurs. This slowly goes on until the inevitable pyorrhœa has begun, with its consequent terrors of treatment, if any, and same ultimate result—full upper and lower cases.

The Remedy.

I have made a series of tests with my own tooth-brush with a view to eradicating this trouble. I found that placing a tooth-brush in an antiseptic for four or five minutes after use did not interrupt the incubation of the bacteria; and it certainly did not render the brush sterile. I have, therefore, come to the conclusion that there is nothing for it but to leave the brush immersed in a fairly strong antiseptic the whole of the time it is not in use.

I have put a sterile brush after use in 1–20 carbolic, and have continued to use it without it becoming infected. This is very hard on the brush, but a very good thing for the tooth-brush manufacturers. The only tooth-brush that will not become slimy with constant immersion in fluid must be made of a much stiffer and thicker material than those that are generally used to-day.

The prevention of much gum trouble lies in the non-use of septic brushes. As tooth-brushes have become a necessity in modern life, great care must be taken to see that they are kept clean in the manner stated. I do not suggest that septic tooth-brushes are the activating cause of pyorrhœa alveolaris, but I do suggest most strongly, that once the public realise this danger and deal with it, the number of cases of pyorrhœa will diminish to the small percentage that existed before the use of tooth-brushes became so prevalent. I do not say that no cases of pyorrhœa alveolaris will exist. Pyorrhœa alveolaris existed before tooth-brushes were thought of. The modern prevalence of the disease is due to the way in which the mucous membranes of the mouth are irritated and their resistance lowered by these septic brushes.

I have traced the source of the disease in Greenland and Iceland. The prevalence there has been put down to the incoming of western civilisation and diet. The Kaffir in South Africa has been similarly affected. The civilised diet and mode of living of the Eskimo and the Kaffir are poles apart, although the origin is the same. The one thing they have now in common is the filthy tooth-brush, and in its train comes the prevalence of pyorrhœa alveolaris.

Conclusion.

In conclusion, I emphasise that pyorrhœa alveolaris is in no way actively caused by the dirty brush; but that the ground is so prepared by this constant irritation that the membranes fall an easy prey to the disease, should other predisposing conditions arise. Whatever may be the activating cause, these filthy brushes are at the root of 90 per cent. of the cases, and the prevention is in the patients' own hands. The few cases which occur independently of brush irritation could all the more certainly be dealt with.

Clinical and Laboratory Notes.

A CASE OF SELF-INDUCED "REDUCTION EN MASSE."

BY PHILIP HAWE, M.B. LIVERP., F.R.C.S. ENG.,
SURGICAL REGISTRAR AND ASSISTANT, NORTHERN HOSPITAL, LIVERPOOL.

THE dangers of taxis in cases of strangulated hernia are, of course, well known, but the following account may emphasise how very little pressure, even by the patient himself, may be sufficient to cause disaster.

A man, aged 30, a bridge-builder, had reduced his right inguinal hernia without difficulty many times during the last five years. Recently he had a *little* more trouble than usual but succeeded in reducing it with only slight discomfort. But after this—with the exception of one small motion, presumably from the intestine below the hernia—constipation became absolute and the symptoms of acute intestinal obstruction developed. Vomiting commenced on the fifth day, and on admission to the hospital on the sixth day the abdomen was moderately distended and the patient rather collapsed. No abnormality was to be found in the region of the hernial orifices nor was there any localised tenderness.

Operation revealed a "reduction en masse"; the whole sac had been displaced from the inguinal canal into a pre-peritoneal position—it was not an example of reduction from a main sac into a properitoneal diverticulum—and the neck of the sac was strangulating three inches of the small intestine contained therein. The gut recovered sufficiently on section of the constricting band and prolonged application of hot saline, to allow of its return into the abdomen. Unfortunately, the patient died from paralytic ileus two days later.

This illustrates how gentle must be taxis, if employed at all, in cases of hernia. It would be unreasonable to discredit the patient's account of the force used by him, or the slight amount of pain he caused himself during the reduction of the hernia, and yet he was able to displace the sac and its contents from the inguinal canal.

I am indebted to Mr. J. H. Rawlinson, of the Northern Hospital, for permission to publish these notes.

ANALYSIS OF SOME UNUSUAL INTESTINAL CONCRETIONS.

BY A. WOODMANSEY, M.Sc.,
ANALYST, HARROGATE CORPORATION.

THE scybala were passed by a patient taking intestinal lavage treatment at Harrogate with alkaline sulphur water—viz., the Harlow Spring. At the second treatment large membraniform casts of mucous matter came away. A similar removal followed each treatment until the fifth, when the patient passed 12 ha

scybala coated with mucus. There was no hæmorrhage. Five of the concretions were taken for examination.

Analysis.

Weight of five scybala (representative of the 12)	2·5 oz.
Moisture and volatile matter (110° C.)	51·6 per cent.
Alcoholic extract, highly fluorescent.	
Aqueous extract (a reddish-brown gummy material)	3·3 ,,
Dry insoluble residue (showed under the microscope a granular appearance but no characteristic structure beyond the presence of a few hair-like fibres)	45·1 ,,

From the dried material the following constituents were isolated. Acid radicles, PO_4, SO_4, and Cl, were not estimated. The percentages are calculated on the undried specimen.

Unsaponifiable fat, cholesterol, &c.	4·5 per cent.
Saponifiable oil	1·4 ,,
Silica and insoluble matter	0·1 ,,
Bismuth oxide	0·69 ,,
Ferric oxide	traces.
Calcium oxide	3·00 ,,
Magnesium oxide	2·45 ,,
Protein substance (calculated from Kjeldahl estimation)	15·6 ,,
Carbohydrate substance (calculated from Fehling estimation)	19·6 ,,

Notes.

Seven weeks previously the patient had taken a bismuth meal prior to radiological examination. As the bismuth content is low it is probable that the scybala were present in the intestine long before the meal. Lavage with saline solution in a nursing home had been unsuccessful in removing the cause of trouble. The inorganic bases apart from the bismuth are normal constituents of excreta.

NOTES ON SEVERAL ABNORMALITIES IN THE SAME PATIENT.

By MAURICE E. M. JAGO, M.B., B.S. LOND.,
SENIOR HOUSE SURGEON, BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.

THE following case is of interest in view of the variety of conditions found :—

A woman, aged 22, was admitted to the Blackburn and East Lancashire Royal Infirmary on May 21st, 1926. She had been recommended for operative treatment for a left inguinal hernia, and a note had been made that she was suffering from phthisis. Preoperative routine examination in the ward elicited the following history and clinical facts.

She had noticed a swelling in her left groin for about six months. For as long as she could remember she had suffered from a bad cough and had received treatment for the same in the Royal Infirmary, Manchester. The family history was good and no history of tuberculosis was obtained.

On examination of the left groin and upper part of the left thigh a swelling appeared when the patient coughed. This swelling was in the upper part of the thigh on the inner side, distal to Poupart's ligament and distal and external to the spine of the pubes. There was an expansile impulse on coughing. The swelling was easily reducible and did not reappear during recumbency except on coughing. A diagnosis was made of left femoral hernia (? saphena varix); there was no varicosity of the veins of the leg.

The patient had a continuous cough. She had pigeon-breast deformity of the chest, but movement on respiration was good. Tactile vocal fremitus was increased on the right side; the right apex was dull to percussion, and on auscultation the breath sounds were bronchial in type. There was suspicion of a cavity at the level of the third or fourth rib, indicated by post-tussive suction. Râles were heard all over the right side of the chest.

On continuing the examination of the chest, cardiac dullness was not obtained on the left side. The position of the heart was eventually discovered to be well to the right side of the middle line, and this was at first thought to be due to a fibroid condition of the right lung. On examination of the abdomen, however, the liver dullness was made out on the left side, while the stomach resonance was under the right costal margin. Finally, on examination of the back, it was noted that the spinous processes of the lower vertebræ were bifid.

An X ray examination revealed complete transposition of the heart, stomach, intestines, and liver. An opaque meal revealed normal gastric and duodenal shadows. No abnormality was seen in the lower ileum, cæcum, and ascending colon, the latter, of course, being on the left side of the abdomen. The right lung appeared smaller than the left, and was less luminous in the upper lobe and middle portion. The film showed irregular mottled density involving especially the middle portion of both lungs. A radiographic diagnosis of bronchiectasis was made.

No operation was performed on account of the condition of the chest, and the patient was discharged on June 16th. Throughout her stay in hospital her temperature was subnormal, the respiration-rate about 20, and pulse-rate 80 to 100.

My thanks are due to Dr. H. C. Lees, under whose care the patient was admitted, for permission to publish this case.

Medical Societies.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE seventeenth annual meeting of this Congress was held at Oxford from July 7th to 9th under the Mastership of Mr. PHILIP H. ADAMS. After the formal opening a discussion was held on the

RESULTS OF OPERATIVE TREATMENT OF GLAUCOMA.

Dr. WILLIAM H. WILMER (Johns Hopkins Hospital, Baltimore) began by referring to the work of von Graefe who, in 1857, wrote concerning glaucoma "the absence of general agreement constitutes an hereditary evil of therapeutics only to be cured by slow degrees . . . The only treatment from which relief can be expected is one that diminishes pressure." That both these propositions are true to-day, said Dr. Wilmer, is attested by the fact that over sixty operative procedures, with many modifications, are on record, all of which are devised solely for the purpose of reducing intra-ocular tension. An analysis of a few of the kinds of operations and their results as reported by various authors is as follows :—

Iridectomy.—482 cases : successful, 63·3 per cent. No late infection mentioned.

Anterior sclerectomy (Lagrange).—777 cases : successful, 72·8 per cent. Late infection (based on 389 eyes), 1·3 per cent. Lagrange's own cases, 104 : successful, 85·5 per cent.

Sclerocorneal trephine (Elliot).—3381 cases, not including 911 eyes operated upon in Egypt : successful, 77·6 per cent. Late infection, 1·2 per cent.

Punch (Holth).—Holth publishes the record of 200 cases in Christiania from 1920 to 1923. The percentage of successes is not given, but he states that there were no late infections, and concludes : "The lowering of the ocular pressure is as good as in the other forms of sclerectomy and, so far, no case of late infection has been observed." Hagen records 52 cases operated by Holth, H. Schiotz, and himself. Of these he excludes 12, confining his tables to 40 cases of glaucoma simplex. Successful, 82 per cent. Butler reports 29 cases : successful, 79·3 per cent. Late infection, 3·4 per cent. Later he reports 39 cases : successful, 66·7 per cent.

Iris incarceration.—517 cases, iridotasis and iridencleisis : successful, 87·4 per cent. Late infection, 0·3 per cent.

Wedge-isolation and small flap. Sclerotomy (Herbert).—The author has given up the former operation for the small flap sclerotomy. The reports are too few to analyse. Butler quotes seven cases (small flap). Successes, 50 per cent., but this in no way indicates the excellent results obtained by the skilful originator himself.

Cyclodialysis (Heine), 1027 cases : successful, 66·7 per cent. No serious complications mentioned.

Dr. Wilmer said that whilst he employs iridectomy, anterior sclerectomy, and cyclodialysis, he more often uses the trephine operation. He presented two series of his own trephine cases.

Series 1 (private cases).—Of these 72 eyes 76·3 per cent. of the whole number have been under observation from 10 to 15 years ; 19·4 per cent. from 5 to 10 years ; and 4·1 per cent. from 3 to 5 years. Successes, 84·8 per cent. ; failures, 15·2 per cent.

Series 2.—35 cases (private and free), trephined within two years (none within four months), are reported for

comparison. Successful, 91·3 per cent.; partial failure, 5·7 per cent.; complete failure, 2·8 per cent.

In these cases, said Dr. Wilmer, success meant a tension of 18 or under (Schiotz reading), with a maintenance or improvement of the vision and the fields of vision as compared with that before operation. Causes of failure were previous venous thrombosis, tuberculous deposits filling trephine openings, traumatic dislocation of lens 10 years after a successful operation, rapid development of immature cataract after hæmorrhage, and repeated retinal hæmorrhages. In 19 of the second series of cases, a Tenon's capsule implant was made use of, a valuable procedure where the conjunctival flap is too thin and as a prevention against late infection.

Dr. Wilmer showed a series of slides of the eyes of rabbits and dogs, upon which anterior sclerectomy, sclerocorneal trephine, wedge isolation, small flap sclerotomy, and iridotasis had been performed. After commenting on the various types of operation, he said that every operator is more skilful in the performance of the operation he selects, but for the average the trephine is more safely and easily performed than the Lagrange or punch operation. It is also suitable for more kinds of glaucoma and in eyes with very high tension. In the Lagrange operation, if the pressure is high, there is more danger of expulsion of the lens and loss of vitreous at the time of the operation or later. Few operators have the skill of the originator of the excellent operation that bears his name. When the surgeon has much operative material, so that he can perfect his technique in both the Lagrange and Elliot operations it is a practical plan to perform an anterior sclerectomy when the tension is below 35 (Schiotz), and to trephine when the tension is higher than this.

Discussion.

Prof. FELIX LAGRANGE (Paris) referred to his performance of sclerecto-iridectomy for the first time in England at the Oxford meeting held in 1906. He had never seen infection follow his operation.

Mr. A. L. WHITEHEAD (Leeds) said that, after trying other procedures, his rule now was to perform iridectomy in case of acute glaucoma and to trephine for chronic glaucoma. An analysis of 120 of his private cases, chosen because the records were more complete than in hospital cases, was as follows :—

Of 38 *acute cases:* 57·9 per cent. were successful, 26·3 per cent. partially successful, and 15·7 per cent. failures.

Of 14 *subacute cases:* 85·7 per cent. were successful, 14·3 per cent. partially successful, and there were no complete failures.

Of 48 *chronic cases* 87·5 per cent. were successful, 4·1 per cent. partially successful, and 8·3 per cent. failures.

Lieut.-Colonel H. HERBERT (Brighton) considered that successful results were obtained with his small flap operation especially if massage was regularly applied afterwards. With regard to iris-inclusion he thought there should be a distinction made between disasters at the time of operation and simple failures to relieve tension, and he felt that there ought to be no danger of sympathetic ophthalmia provided that proper aseptic precautions were undertaken before the operation. His belief was that the future lay with the small linear wounds either with or without iris inclusion.

Mr. MALCOLM HEPBURN (London) said that his operative experience had forced him to the conclusion that not all forms of glaucoma could be explained on the same pathological theory, but that different pathological conditions accounted for the various types of the disease. It followed from this that the results obtained by applying one type of operation for all forms of glaucoma would be variable, and it was necessary for the surgeon in order to be successful to select the type of operation suitable for the case he had in hand. Good results would depend upon this and upon operating early; bad results would follow late or unsuitable operation, mistakes in technique and secondary complications over which the surgeon had no control.

Lieut.-Colonel R. E. WRIGHT (I.M.S.), agreed with Dr. Wilmer in his support of trephining as opposed to cyclodialysis and was interested in the method described by him for obtaining an extra cover of tissue over the trephine hole. He also favoured a broad iridectomy in cases in which he feared a "desquamation of uveal tissue" or "iritis" as it was termed. Massage was of value in all cases although there was really no necessity for it after trephine operations.

Dr. C. F. BENTZEN (Copenhagen) reported the results of 72 cases of trephining in which he had separated the conjunctiva from the limbus instead of from above as in the usual Elliot method. Of the 72 cases, 6 were those of buphthalmia, 4 of acute glaucoma, 14 of absolute glaucoma, and 48 of chronic glaucoma. No case of late infection had occurred. There were poor results in the buphthalmia cases and also in those of absolute glaucoma. In the acute cases the results were moderately good and in the 48 cases of chronic glaucoma there were 77 per cent. of successes.

Prof. J. SZYMANSKI (Wilno) described his modification of Elliot's operation in which he made use of a large trephine cutting obliquely a semi-circle of sclera which was then excised with scissors.

Mr. HARRISON BUTLER (Birmingham) referred to the mental complications of operations on elderly decrepit patients. In iridencleisis operations he had found that no result was obtained—i.e., neither fall of tension nor untoward complications. After trephining a shallow anterior chamber might follow, which if persistent led to the formation of a nuclear cataract. He had observed the fall of tension in the fellow eye after a successful operation on the one.

Mr. R. C. DAVENPORT (London) referred to the analysis of some 536 cases of glaucoma, 405 being primary, which had been trephined at Moorfields by various surgeons in the last five years. The results obtained were according to vision only. These had been reported fully in the *British Journal of Ophthalmology* (1926). In only two of the 536 cases did mental disturbance occur; there were 14 cases of late infection, of which, however, only 8 were definitely in connexion with the trephine hole.

Dr. HARALD GJESSING (Drammen) spoke of having had 81 per cent. of good results by Holth's method the cases having been under observation from 6 months to 11 years.

Mr. J. GRAY CLEGG (Manchester) considered that detachment of the choroid was a much more frequent result than was usually thought, even occurring, he thought, in 10 per cent. of cases.

Mr. B. GRAVES (London) referred to cases of persistent low tension after operation, in one of which shrinking of the eye had followed.

Mr. D. V. GIRI (Eastbourne), speaking of the fluorescin test for filtration, commented on the variations in tension which occurred during the day.

Lieut.-Colonel A. E. J. LISTER (Bristol) asked for an expression of opinion on the question of low tension after operation, which he regarded as a very alarming complication.

Dr. WILDER (Chicago) said that all the operations had been tried in America, and the fact that no definite conclusions had been reached was good evidence that none of them was perfect. The best thing would be for one surgeon to perform all the various procedures for comparison. He personally was in favour of the iris-inclusion operation, having only had one unsatisfactory case in 100 operated on by this method.

Dr. WILMER, in reply, said that expulsion of the lens after the Lagrange operation was, according to the literature, a not uncommon complication and the accident had once been recorded after a trephine operation. He had never experienced separation of the choroid in his own practice, but had seen two cases in consultation, both of which promptly got well. He had had cases of very low tension after both trephining and the Lagrange operation, but had

never had an eye in which there was delayed formation of the anterior chamber.

DEMONSTRATIONS AND LECTURES.

On Thursday afternoon, after Prof. LAGRANGE had read a paper on Fistulisation of the Glaucomatous Eye, demonstrations were held in the Scientific and Commercial Museums.

Lieut.-Colonel WRIGHT demonstrated Green's apparatus in intracapsular extraction of cataract and his own method of blocking the main trunk of the facial to prevent squeezing in cataract operations. He also showed a series of histopathological slides of orbital neoplasms.

Dr. J. BURDON COOPER (Bath) demonstrated a new astigmatic test chart.

Dr. THOMSON HENDERSON (Nottingham) demonstrated in an ox eye the membranous nature of the ligamentum zonulæ ventis by injecting air through the ligament into the canal of Petit, thus showing that it is a closed space.

Dr. H. H. TYSON (New York) exhibited a series of skiagrams of the optic foramen showing the variations in size and shape from the normal, and demonstrated the effect which the narrowing of the canal had upon the optic nerve, causing atrophy.

Mr. D. V. GIRI showed a photograph of an apparatus for red-free ophthalmoscopy and a lid-retractor which raised the lids free from the globe as well as retracting them.

Mr. F. A. ANDERSON (Shrewsbury) showed an operating light obtained by a series of small lamps.

Mr. B. CRIDLAND (Wolverhampton) showed the drawing with specimen and slides of a case of cholesterin crystals in the anterior chamber.

The chief feature of the proceedings on Friday morning was the Doyne Memorial Lecture by Prof. K. K. K. LUNDSGAARD (Copenhagen), whose subject was the Pneumococcus in Connexion with Ophthalmology. He showed a chart of the incidence of the pneumococcus on the normal conjunctiva as determined by various observers since 1909, the latest record being that obtained by himself in 1925—namely, 6 per cent. The various types of the micro-organism were described and charted according to their virulence. Other charts were shown giving the incidence according to age and seasonal variation. At the end of his lecture Prof. Lundsgaard was presented with the Doyne Memorial Medal for the year.

Other papers were delivered by Dr. CARSTEN EDMUND, Lieut.-Colonel WRIGHT, and Dr. HOLGER MAHLERS.

Friday afternoon was spent at the Oxford Eye Hospital where a series of interesting cases were shown by the Master, and by Mr. HARRISON BUTLER and Mr. HARRIES JONES. On Saturday morning papers were read by Dr. COOPER, Dr. MARGARET ROBSON, Dr. HARALD GJESSING, and Mr. GIRI.

The annual dinner of the Congress, which was well attended, was held in Keble Hall on Thursday evening with Prof. ARTHUR THOMSON as chief guest. Members who attended from abroad, in addition to those already mentioned, included Dr. H. Friedenwald (Baltimore), Dr. Bernard Samuels (New York), Dr. Birger Malling (Bergen), Dr. A. Verwey (Durban), Dr. R. G. Stott and Dr. A. S. Anderson (Australia), and Dr. Pandit (India). The total membership of the Congress is now over 400, and the attendance this year was well over the average.

BETHNAL GREEN HOSPITAL.—New casualty and receiving wards have been opened at Bethnal Green Hospital. Owing to the heavy increase in the number of casualties brought there by London County Council ambulances, the work of the hospital steadily develops. In 1923–24 these cases numbered 266; in 1924–25, 460; and in 1926, 752. In the new wards there is good accommodation for men and women.

WANTAGE COTTAGE HOSPITAL.—The new Cottage Hospital at Wantage was opened recently by Princess Helena Victoria. The hospital, built in red and grey concrete, faces south, and contains private wards for both men and women, as well as general, maternity, and children's wards, all having access to a verandah. There is an operating theatre, and the latest ultra-violet ray treatment is provided in the clinic.

Reviews and Notices of Books.

PREVENTIVE MEDICINE.

An Introduction to the Practice of Preventive Medicine. Second edition. By J. G. FITZGERALD, M.D., LL.D., F.R.S.C., Professor of Hygiene and Preventive Medicine, and Director, School of Hygiene and Connaught Laboratories, University of Toronto. London: Henry Kimpton. 1927. Pp. 792. 35*s.*

ADAPTATION of the principles of hygiene to the peculiarities of local climates and social conditions, together with the rapid extension of public health practice, has led in recent years to the production of numerous text-books. Within the past year we have reviewed several manuals which cover, in a sense, common ground, but in which the point of view varies with the social development of the country for whose nationals the books are intended. Thus, for India apparently sanitation is still the most urgent need; British text-books bravely try to cover the whole field of hygiene and tend, in consequence, to be unattractive to the reader; while the American books devote most space and the best writing to the epidemiological, bacteriological, and immunological aspects of the public health. In both American and British publications the newer branches of hygiene, which aim rather at the promotion of health than the prevention of disease, are beginning to encroach upon the space formerly taken up by the discussion of those engineering problems which figured so prominently in the sanitary science of last century. The book under review follows the American pattern, giving first place, after a brief statement of the aims of hygiene, to the prevention of the communicable diseases and devoting several chapters to this subject. Other chapters deal with water, milk, foods, and air (written by Mr. H. M. Lancaster), diet, &c. (by Dr. Andrew Hunter), sanitation (by Mr. Peter Gillespie), maternal and child hygiene, school hygiene and clinics, vital statistics, public health organisation and public health education, while a chapter on industrial hygiene is contributed by Dr. J. G. Cunningham and Dr. R. M. Hutton. Illustrations throughout are derived mainly from the records and experiences of Canada or the United States, and the writers have drawn largely from American current public health literature. Reference is made, however, to most of the really important European work of recent years, with the exception of Prof. W. W. C. Topley's epidemiological studies. Some of the statistics quoted might have been more useful if they had been submitted to a process of digestion, but they will be of value to those who have no means of access to the actual government or state records from which they have been culled. This manual should prove valuable to Canadian students and practitioners of preventive medicine, and will find readers also in this country.

PREVENTIVE MEDICINE AND HYGIENE.

Fifth edition. By MILTON J. ROSENAU, Professor of Preventive Medicine and Hygiene, Harvard Medical School. London and New York: D. Appleton and Co. 1927. Pp. 1458. 42*s.*

SINCE the first edition appeared in 1913, this text-book has ranked, not only in America but also in this country, among the few standard works on public health. It has now undergone very careful revision in order to eliminate all that has been shown to be unsound as the result of the work of the past five years. Several hundred pages of the former edition have been omitted, and new subjects have been introduced, such as the psycho-analytic approach to sex hygiene, the prevention of cancer, the conservation of vision, periodic physical examinations, and so forth. Among the sections which have been largely re-written are those on scarlet fever, scurvy, rickets, and pellagra. This book differs from most English text-books in the

relatively meagre amount of space given to sanitation in contrast with that devoted to the prevention of communicable diseases. This feature will appeal to the modern health officer of all countries, although it must be remembered that the immigrant and unstabilised character of the American population is perhaps associated with greater epidemic menaces than the older civilisations have to meet. The established American views on such subjects as disinfection and vaccination are set out, and with these we find ourselves in complete agreement. Generally it may be said that Rosenau discards none of the hard-earned knowledge of the pioneers, but places it in proper perspective with the newer thought on sanitation and epidemiology. It is a pity that, probably as the result of hasty writing, this excellent book is marred by occasional lapses in literary style.

THE ÆTIOLOGY OF BERI-BERI.

Beiträge zur Geschichte der Erkennung der Beriberi als Avitaminose. Von Prof. Dr. G. GRIJNS, Landbouwhoogeschool Wageningen, Holland; Fortschritte der Naturwissenschaftlichen Forschung. Herausgegeben von Prof. Dr. EMIL ABDERHALDEN, Halle A.S. Neue Folge, Heft 1. Berlin and Vienna: Urban and Schwarzenberg. 1927. Pp. 32. Mk.3.

AN introduction by the editor, Dr. Emil Abderhalden, explains that this pamphlet recapitulates in German the early work of Prof. G. Grijns on beriberi and polyneuritis gallinarum, which had appeared for the most part in Dutch and in periodicals not easily accessible. The first few paragraphs are devoted to Dr. C. Eykman's well-known original observations, beginning in 1889, when he first noticed the spontaneous occurrence of polyneuritis among fowls living on polished rice. Grijns followed Eykman in 1896, and his researches from then on are summarised. He showed, for instance, that supplements of mineral salts had no beneficial influence in polyneuritis gallinarum; that the origin of the rice was indifferent; that freshly milled rice was as productive of the disease as that which had been milled a long time, and that additions of fat were not helpful. He found that *Phaseolus radiatus*, the katjang idjo bean, as an addition to the diet, was an excellent preventive against beri-beri. He marshals evidence and discusses the facts then known as to whether the disease is due to a toxin or a deficiency, and was himself already then inclined to favour the latter view. He brings the account of his work down to 1911, when the vitamins, both as a name and as a concept, were well established.

Prof. Grijns is well known to most students of beri-beri as the discoverer of the katjang idjo bean, the use of which has played so large a part in the fight against the disease in the East. He is also familiar as the maker of important contributions to the pioneer work on the disease; Casimir Funk speaks of him as "the first worker to express clearly a conception of beri-beri which holds good to this day." The value of his contribution is undoubted, but whether there was a demand for the republication of his work at the present time and in the present form it is less easy to say. Possibly owing to the neglect which the vitamins suffered in Central Europe, owing to the war, this new summary in German may fill a greater need than it would do here. It is certainly handy and well arranged.

JOURNALS.

THE QUARTERLY REVIEW OF BIOLOGY. Vol. II., No. 2, June, 1927. Baltimore: Williams and Wilkins Company. London agents: Baillière, Tindall and Cox. $5 per annum.—Prof. Raymond Pearl's review continues its useful career in helping to keep those who are not professional biologists from falling too far behind the rapid progress which is being made in various directions. This number opens with a long article on the innervation of muscle by Dr. M. Hines, which deals with the question of plurisegmental innervation, red and white muscle, muscle spindles, and—which will be of special interest to our readers—with the relation of the sympathetic to skeletal muscle and the work of Hunter and Royle; tone remains as mysterious as before.—The next essay is on animal life in hot springs, especially those in Yellowstone Park, by C. T. Brues. An account is given of the varied collection of live things which live in such places; elementary plants can live in water at more than 70° C., but the adaptation of higher invertebrate animals is much less—45° C. or thereabouts as a maximum.—Prof. A. Brachet, of Brussels, writes on the present state of knowledge of the germinal localisation of the factors for development in the egg, and Prof. L. V. Heilbrunn on the viscosity of protoplasm.—Prof. F. A. E. Crew continues his clear exposition of abnormalities of sex, and in this instalment considers the instances in which the sex, as determined by the chromosome equipment, is overridden by other factors, a matter on which the masculinising tumours of the adrenals might receive more attention.—Lastly, Dr. W. K. Gregory philosophises on the lateral aspect of the skull from fishes to man, and the number ends with 26 pages of useful book notices. Medical libraries swell to bursting nowadays, but this is a journal which they will do well to take.

Reports and Analytical Records.

AUSTIN'S ORANGE MARMALADE (SUGARLESS).

(MANUFACTURED BY J. E. AUSTIN AND CO., LTD., ST. JAMES' WORKS, CROMWELL-ROAD, KINGSTON-ON-THAMES.)

THIS product has the appearance, smell, and substantially the flavour of ordinary marmalade, and is distinctly sweet to the palate. When analysed the following results were obtained:—

Moisture	62·00 per cent.
Mineral matter	0·38 ,,
Matter insoluble in water	1·60 ,,
Sugar	1·90 ,,
Citric acid	0·54 ,,
Soluble extractives, including glycerol, pectinous matter, &c.	33·58 ,,

Gelatin and confectioner's glucose were absent and saccharin, formalin, benzoic, salicylic, and boric acids were tested for with negative results. The minute trace of sulphurous acid was less than is permitted by the recent regulations.

The sweetness is due to glycerol, and the statement of the manufacturers that the marmalade is free from added sugar and therefore suitable for diabetic patients is a correct one.

HINDES' BROWN HAIR TINT.

(PREPARED BY HINDES, LTD., 60, PARKER-STREET, KINGSWAY, LONDON.)

We have examined this well-known hair tint, the manufacturers having supplied us with the formula for our confidential consideration. We find that its composition is what it is stated to be. Hindes' brown hair tint contains no scheduled poison.

KIA-ORA LEMON SQUASH.

(KIA-ORA, LTD., BLACKFRIARS, LONDON, S.E. 1.)

This well-known lemon squash is prepared from lemons and sugar. For consumption as a beverage it is mixed with an appropriate amount of water or soda-water. On analysis the following results were obtained:—

Specific gravity	1·1695°
Sugar	33·1 per cent.
Citric acid	2·83 ,,
Glycerine	5·00 ,,
Ash	0·30 ,,
Water and lemon pulp	58·70 ,,

A small amount of sulphurous acid was found, which serves the purpose of a preservative. From the results it will be seen that "Kia-Ora" is a genuine lemon juice which has been sweetened by the addition of sugar and glycerine.

THE LANCET.

LONDON, SATURDAY, JULY 23, 1927.

THE ENCROACHMENT UPON INDIVIDUAL PRACTICE.

THE position of the general practitioner in the face of modern developments, alike in social legislation, in medical knowledge, and in technical equipment, has been seen for some time to present problems of growing perplexity. Similar problems have attended similar evolution before now, but to-day their complexity is such as to warrant apprehension. Some of the debates at the Representative Meeting of the British Medical Association, held in Edinburgh at the end of last week, revolved definitely round certain of these problems, while in the course of other debates it was clear that their existence was present in the minds of the speakers and was influencing their thoughts and their words. The fact that, save in the broad desire to do well by the public, there was no complete unanimity of medical opinion in these debates was not only what might be expected, but it is a proof both that the existence of grave difficulties is realised widely and that the need is felt for the earnest coöperation of all concerned if the conduct of medical practice is to maintain the spirit—the admirable spirit—of the past. It is now more patent than ever that the positions which arise in professional life are not only those which affect a fair adjustment of the interests of the public in relation to the interests of the medical profession as a whole. The medical profession, as a whole, cannot under the existing pattern of public affairs have more than one common concern—namely, that of promoting the health of the people, a concern which they share with the public. The scope of the all-round practitioner, of the specialist, and of those engaged in official or institutional positions cannot be subservient to identical practical desiderata, and it is the diverse nature of the claims of medical practice that is making so hard the arrival at definite decisions.

The general practitioners are those who really conduct the practice of medicine in the land, and the questions at issue concern not only the possible encroachment upon their natural duties by alterations in the law of the land, but concern also the encroachment conducted, with the best of motives, by State or municipal authorities, through the medium of medical officers or of various specialists, the latter of whom may be taken to represent the class of medical men which by equipment and opportunity is regarded as a leading one. It is imperative for the settlement of lines along which the medical practice of the country can proceed to the advantage both of the public and the medical profession that the sections of the latter, thus crudely set out, should not antagonise each other, but should realise that in overlapping territories of duty and responsibility joint efforts should be made for the public good. This should be the simpler because the sections of the medical profession are far more divided in appearance than in reality. For example, that large proportion of general practice which is represented by the work done under the National Insurance Act can itself be roughly classed as State practice, but its officers are definitely concerned with the individual care of patients, which they give in accordance alike with time-honoured methods and new knowledge. The quality of the service rendered is well standardised and has admittedly undergone marked improvement as the machinery for conducting general practice has been modified to bring the domiciliary care of the panel patient more closely into line with the traditions of private practice. That is all to the good, but it is also to the good that the practitioners of medicine along particular lines should form groups in order that their experiences may be collated and that definite plans of procedure should be evolved. Such men bring to the common task of maintaining and improving the health of the country the knowledge which can only be obtained and the talents which can only be kept bright by the intensive nature of their studies. But the more just their views of the good which they can accomplish the more clear will be their apprehension of the fact that the benefits which they can bestow will be vastly enhanced by close coöperation with those who have the charge of the general health of their patients. It follows that the specialists should regard themselves as consulting practitioners, anxious to take into consideration, when formulating any action, the opinions of the practitioners, and ready to explain to their colleagues the purposes in their minds. A similar fusing of knowledge and duty between practitioners and the officers of sanitary or lunacy services is possible, and it is especially when questions of early diagnosis arise that joint action is of public benefit. There is room under the natural expansion of the National Insurance Act for the linking up in this way of the sections of the profession, and the policy of the Ministry of Health should be directed broadly to those ends.

These are the considerations which should be clear to those who in the cause of the public propose to provide, by public or voluntary means, the facilities for medical treatment, and their significance should not be missed by commercial enterprises, if it is desired to work harmoniously with doctors. It is no sign of progress that the pattern on which individual medical practice has been conducted so splendidly and so long should be destroyed. A humorist has pointed out that those who career through the old villages of England in charabancs may soon desire to have the villages, which they purport to be visiting, removed, because the ancient byeways and projecting buildings impede the transit of the vast vehicles. If commercialisation of medicine should grow to the proportions of the charabanc industry, we may well ask if much that is beautiful and time-honoured in our conduct of practice is not threatened by the very machinery which is designed to make that practice more efficient.

VENEREAL DISEASE AND PROFESSIONAL SECRECY.

THE medical profession has not had long to wait for a fresh illustration of the difficulty and invidiousness of its members' position when they are brought into the witness-box to give evidence as to their treatment of patients suffering from venereal disease. At the Birmingham Assizes last week a medical practitioner from the Birmingham General Hospital was subpœnaed, on behalf of a wife petitioning for divorce, to give evidence concerning the treatment of her husband at the hospital in 1924. The witness naturally protested, and not merely on the grounds of professional tradition. He stated that he was not at the head of the hospital department concerned in 1924; a number of doctors were engaged in this work, and all had their own papers which were their personal property; he himself had no authority to produce other doctors' papers. Mr. Justice MCCARDIE, a judge who has often shown sympathy with the medical point of view, found himself obliged to say that the witness was entitled to no privilege, but must produce the documents and information. If he did not do so, every medical man and a number of officials from the hospitals would have to be called to the court, and ultimately the documents must be made available. If information were not given that should be given, and if documents were not produced which should be produced, the law, said the judge, would be enforced, and the doctor refusing to obey its order would be sent to prison. The hearing was adjourned until July 18th, in order that the doctors concerned might be subpœnaed. On resumption Mr. Justice MCCARDIE asked the learned counsel appearing for the petitioner whether he had considered the effect of the special obligation of medical secrecy in cases of venereal disease. Counsel argued that the Local Government Board's Regulations of 1916, which specifically direct non-disclosure, had no power to override the witness's duty to answer questions. This argument the judge accepted and upheld. His lordship said that the medical profession normally was under the duty of keeping inviolate the secret knowledge that its members may gain from treating a patient; indeed, they might become liable to a civil action for damages if without lawful excuse the duty of confidence was broken; but in a court of law the doctor had no privilege similar to that held by a solicitor or other legal adviser, and he was not privileged from compulsory disclosures of communications, however confidential. A further point arose, he continued, in the present case as to whether doctors were in a specially privileged position owing to the fact that they were acting in a department under the control of the Ministry of Health through the local health committee. In his view there was nothing in the regulations, nor in any regulations he had heard of, which saved a doctor from the obligation of disclosing —if ordered to do so by the court—all the information he might have of the facts he had gained while acting under the regulations.

In this unfortunate conflict of loyalties which has been thrust upon the medical profession two things are clear. In the first place a fresh situation has arisen in which the immemorial professional tradition of secrecy has to face a new challenge on a wide front. New arrangements, officially organised, have involved the treatment of venereal disease on an unprecedented scale. Simultaneously the law has made new demands for evidence. Recent years have witnessed a huge increase in divorce petitions, partly because of the social unsettlement of the war period, partly because divorce has been made easier for the wife, and partly (indeed mainly) because of the remarkable development of facilities for poor petitioners. To relieve the law-courts in London, matrimonial causes have been made triable locally at assizes with greater local publicity. In so far as this class of litigation gives occasion for medical evidence of venereal disease, the occasions have been lately multiplied. Meanwhile another change in the law has enabled a married woman to apply for a separation order on the ground that her husband has insisted upon marital relations while knowing himself to be suffering from venereal disease. Here is fresh occasion for inviting the doctor into the witness-box, and here it is not a case of the patient waiving his or her right to secrecy, but of a doctor giving evidence against the legal interests of the patient.

The second point which is clear is that the Ministry of Health cannot leave matters where they stand. Official utterances proclaim that it is peculiarly necessary to maintain strict professional confidence if venereal disease is to be combated; official regulations enact that secrecy is a legal obligation. All this is meaningless if judges can insist upon full disclosure. Hitherto many have thought it possible to compromise by way of protest on the part of the medical witness. But if protest is to be treated as a mere formality, if a hospital doctor is to be treated as though he were the secretary of a limited company and is to be compelled to produce confidential documents belonging to other practitioners merely because those documents are within the hospital walls, the public will soon learn to distrust the alleged secrecy which the Ministry of Health professes to ensure. Will the Ministry make it clear by regulation or, if necessary, by Act of Parliament that the promise of non-disclosure is genuine and inviolable? If not, it would be only fair to the patient to qualify the promise and to inform him, when he comes for treatment, that not only can secrecy not be ensured, but that—in the language used to the suspected criminal—anything he may say will be taken down and used in evidence against him.

GLAUCOMA.

OF the more serious problems of ophthalmology that await solution the problem of glaucoma is as important as any. Many conditions, of course will cause a pathological rise of intra-ocular tension and many factors are involved, but it is to primary glaucoma, acute and chronic, that most attention has been given. The ætiology and pathology of these states is being investigated in various directions. The physiology of the intra-ocular fluids, their relation to the vascular and nervous systems, and the biochemistry of the lens and vitreous under normal and abnormal conditions, have all to be put upon an unassailable basis before other factors can be considered. Anatomical states, normal and pathological, necessarily play their part, and much attention is being devoted to these also. More definite progress, however, is apparent along the lines of diagnosis, treatment, and prognosis. Tonometry, for instance, and careful methods for examining the whole visual field have greatly helped in early detection of the glaucomatous state, though, in any given case, it is still essential to collect all available clinical evidence; to depend on any one diagnostic factor is unsound.

Acute glaucoma is less of a surgical emergency than it was, for immediate medical treatment often improves the condition enough to allow operation under more favourable and quieter conditions. When this improvement cannot readily be brought about, the classical iridectomy is the operation of choice, and though done under difficulties it shows a very fair measure of success. Although research and experiment in the use of adrenalin and other non-surgical agents have had striking results, the limitations of medical treatment in all forms of glaucoma are being better realised. At the Oxford Ophthalmological Congress, of which we publish a report on p. 173, the varieties of operative treatment were carefully reviewed. The results, it was shown, were on the whole very satisfactory, though opinions differed about the soundest surgical methods of securing and maintaining satisfactory tension in the eye without excessive mutilation or undue risk of infection. The two that found most favour were permanent fistulisation of the angle of the anterior chamber beneath the conjunctiva, and deliberate and permanent subconjunctival inclusion of iris tissue in a scleral wound. Results of the latter method, chiefly from continental surgeons, were shown to be very good, and the case they made out seemed too complete for attack on the ground—so firmly held by ophthalmic surgeons—that any entanglement of the iris in a perforating ocular wound is a source of grave danger and anxiety. Prof. FELIX LAGRANGE, of Paris, very ably outlined the indications for, and requirements of, fistulisation of the eye, advocating the method he devised and originally described at Oxford many years ago. In his hands, and those of others, the operation has given excellent results. The British surgeons and Dr. W. H. WILMER, of Baltimore, who opened the main discussion, reported considerable success—in more than 80 per cent. of cases—with the Elliot trephine operation, which is probably easier to perform than Lagrange's anterior sclerectomy. The dangers of the thinly-covered trephine aperture, with the risk of late infection, were freely discussed, and Dr. WILMER described the method he has evolved of laying a graft of Tenon's capsule over the aperture so as to ensure a firmer covering beneath the conjunctiva.

The lesson of the discussion seemed to be that any of the well-recognised procedures will give a good result—especially in early and favourable cases of chronic glaucoma—provided it is carried out by a capable surgeon who is used to technique. If this is true, progress is unlikely except from further ætiological research, from sorting out the various types of the disease, and from learning their association with altered intra-ocular volume, gradual or precipitate, under normal or abnormal anatomical and physiological conditions. It is to be hoped that surgery will be needed less and less as time goes on, and that, where it is required, the special indications for particular forms of operation may be more clearly defined.

INDEX TO "THE LANCET," VOL. I., 1927.

THE Index and Title-page to Vol. I., 1927, which was completed with the issue of June 25th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Annotations.

"Ne quid nimis."

RESEARCH ON ENZYMES.

IN all branches of human endeavour a few singularly gifted individuals have been able not merely to achieve epoch-making work themselves, but to provide a continuing source of inspiration to their followers. Such an individual was Michael Faraday, and his investigations on "the power of metals and other solids to induce the combination of gaseous bodies" served as a starting-point for research on those change-inducing and accelerating bodies which Berzelius in 1837 named catalysts. The functional similarity of inorganic catalysts, such as platinum, to those organised ferments of which yeast is a type led to much research in both classes. It was probably the dissimilarity which caused Kühne, in 1878, to give the name of enzyme to those catalysts which could be extracted from yeast and other organisms of the same kind. The simpler inorganic catalysts are characterised by the wide range of actions which they will accelerate, whereas the enzymes are highly specific in their action. In his Faraday lecture delivered before the Chemical Society on May 18th, Prof. R. Willstätter, whose work on chlorophyll and on the blue and red pigments of flowers is of outstanding merit, discussed problems and methods in enzyme research. The subject is not simple, and it is probable that few of the large audience carried away much more than a mental picture of a vast and almost uncharted ocean. The printed lecture in the June number of the Society's journal makes it possible to form a clearer notion of what is definitely known. Frankly, this does not seem to be very much, although there is no doubt that work is being done upon the right lines. We are beginning to know what enzymes are not. A. Fodor supposed the saccharase of yeast to be substantially identical with a carbohydrate yeast-gum, but now this enzyme has been wholly freed from yeast-gum without change of activity. E. Fischer and others deduced that the enzymes "are derived from proteins and possess a protein-like character." Lipase, peroxydase, saccharase, and other enzymes can be so purified that the protein-reactions disappear completely. Other facts lead to the conception of the enzymes as peculiar organic compounds, and suggest the problem of isolating them in a state of purity. The task of increasing their concentration involves the measurement at every stage of the activity of the product obtained. The gentlest means must be adopted, and of late years very selective adsorption on specially prepared surface-active substances has been used. This is a process adopted in 1842 by A. Vogel for the isolation of pepsin, and abandoned for a long time, but revived about 20 years ago by Michaelis and Ehrenreich. The behaviour of the adsorbed bodies changes as the enzyme becomes more concentrated; for example, after purification to a certain stage by fractional adsorption, pancreatic amylase, which may be adsorbed by alumina under certain conditions, is no longer adsorbed by alumina gels of excellent adsorptive power. "The adsorption of enzymes is determined by chemical peculiarities which cannot be predicted."

The actual quantities available are small. "Thus the enzyme from 14 kilos of fresh brewer's yeast was adsorbed by 1 gramme of aluminium oxide and the adsorbate weighed 2·5 grammes"—under 0·02 per cent. Vegetable peroxydase in early stages of preparation contained sugar groups and about 0·5 per cent. of iron, apparently characteristic constituents. When its purity was raised fivefold by adsorptive methods the carbohydrates had disappeared and the iron-content had fallen to 0·06 per cent. Then a new property—a reddish-brown colour—appeared. Added to these difficulties are many others. Thus

the optimum pH for an enzyme's action may vary according to its degree of purity. Lipase in the human stomach, unlike pancreatic lipase, has its optimum action at pH 5–6; and the same is true for the stomach of the dog. After purification human gastric lipase has its optimal activity in alkaline solution at pH 8. Willstätter says "the only property of the enzymes which is independent of the purity is, as far as we know, their qualitative specificity; their adaptation to a definite set of reactions determined by constitution and configuration." This is certainly a hopeful circumstance. A substance which under all vicissitudes retains its most characteristic property will almost certainly be isolated. The history of organic chemistry shows that this is only a preliminary stage to ascertaining its constitution and to its ultimate synthesis. Willstätter and his school may only succeed in adding to the equipment of investigators in this region, but it seems not unlikely that the patience and brilliant insight which made green leaves and flowers reveal their secrets will penetrate some of the mysteries of the organised ferments so closely associated with the life of man.

AURAL VERTIGO.

THE *Bristol Medico-Chirurgical Journal* (1927, xliv., 119) publishes an interesting little article by Mr. E. Watson-Williams, in which he distinguishes the classical, or rotatory, vertigo from the other less well-marked forms, which vary from a vague sense of impaired equilibrium to feelings that the patient or his surroundings are moving up and down. In true rotatory vertigo the sensation is that the sufferer, or his surroundings, or both, are turning round and round; the sensation of turning is concise and definite, and even years after a slight attack the patient's description is clear and vivid. The apparent rotation is nearly always in the transverse plane—that is, in the plane of the base of the skull. Mr. Watson-Williams makes the point, which is not new but is often overlooked, that vague feelings of vertigo may or may not be due to aural disease, whereas this definite rotatory vertigo in the absence of cerebral trouble is always due to it; the symptom may occur without tinnitus and even without deafness. He also makes a more novel point, that the nausea of vestibular origin is usually worse in the morning, and that patients suffering from it have therefore no appetite for breakfast, though they may eat their other meals heartily. Attacks of aural vertigo are so often ascribed by the patient to biliousness that it is well worth while to insist, with Mr. Watson-Williams, that this definite rotatory vertigo is always due to disturbance of the mechanism of the labyrinth.

BIOCHEMISTRY AND MEDICINE.

A LARGE proportion of the funds available for medical research are nowadays allotted to laboratory workers whose investigations are apparently remote from the problems of the bedside and consulting-room. This policy is justified by the history of medicine and is only dangerous when allowed to bring clinical work into disrepute. If to-day the trend of ancillary research is largely towards biochemistry that is because this science offers the largest uncultivated areas to the pioneer. The horizons are illimitable and the land is rich; all that is necessary is its exploitation. For centuries there have been extending settlements around the coast from which the old world of medicine has drawn new life, but until recently only a few individuals have devoted their lives to exploring the hinterland. Now at last these isolated journeys are being correlated and the country between them begins to appear upon our maps. Fortunately, there are more and more benefactors ready to finance the survey and development of this new territory in the interests of medicine, and an example of their wisdom is the Institute of Biochemistry opened on Wednesday last at the Middlesex Hospital. This admirable department will be directed by Prof. E. C. Dodds, who has himself brought back much that is valuable from his expeditions into unknown and difficult country. As he pointed out at the opening ceremony at the Institute (reported on p. 195), it is apparent that biochemistry "has already given us great and generally admitted benefits which are a tremendous encouragement to the pursuit of the study." The victories of the pioneers, he said, have already passed into the routine of medical practice; but while so much remains unknown the investigators—however many—are still pioneers. The new Institute will be an admirable starting-point for fresh endeavour.

CHARLES CREIGHTON.

WE regret to announce the death of Dr. Charles Creighton, the learned epidemiologist, which occurred on Sunday, July 17th, at Upper Boddington, where he had lived for some time in retirement. He was in his eightieth year, and will be but a memory to most students of medical history, while his industry and erudition, which will be commented upon in a future issue of THE LANCET won for him no commensurate position in the world.

BASAL METABOLISM IN THYROID DISEASE.

Dr. Eggert Moller, of the University of Copenhagen has recently published [1] investigations, by the Krogh method,[2] into the basal metabolism in thyroid disease. His results are interesting, but serve rather to prove the usefulness of this particular method than to throw any new light on the problems of basal metabolism in thyroid disease. The Krogh closed circuit apparatus seems to possess certain advantages for clinical work, the chief of which is its simplicity; several estimations can be made within an hour, and a graphic record provides an accurate control of the patient's respiration and enables the observer to read off the oxygen consumption directly from the curve. The results have been found to agree satisfactorily with those obtained by other methods. Opinion is almost unanimous at the present time that this test is the best guide to the state of activity of the thyroid gland, and though, like all laboratory tests, it has its limitations, it offers information which clinical observations by themselves could not supply. A large number of records of the basal metabolism in thyroid disease have now been made, both in America and Germany and in this country. Dr. Moller's findings agree closely with them. He again raises the question, however, whether the metabolism is always above normal in Graves's disease. A few years ago J. H. Means [3] called attention to a group of what he called borderline cases, in which the clinical signs of the condition were well marked though normal metabolic readings were obtained. Dr. Moller has found the same thing in his series of patients, and he too is of the opinion that a normal metabolism should not exclude a diagnosis of Graves's disease. It must be remembered that there are certain conditions in which the basal metabolism will give a frankly incorrect impression in diagnosis, unless the previous history of the case is accurately known. For instance, patients with myxœdema who have been receiving thyroid extract, or those with Graves's disease in a period of remission, may still retain many of the phenomena of the disease, and yet show a normal metabolism. These considerations show that any slavish adherence to the test as an index of diagnosis is inadvisable. The value of estimating the basal metabolism seems to lie especially in the differential diagnosis of doubtful cases and in following the effects of different methods of treatment. There is no doubt

that since the introduction of this test the usefulness of certain therapeutic measures has been placed on a surer footing. This is notably the case with the various forms of operation. When this kind of treatment was first undertaken, the largely subjective and impressionist reports about the results were unfavourably received by the profession. Nor did sceptics become convinced until estimations of the basal metabolism were employed to show numerically what had been accomplished. The same is true of the treatment of Graves's disease by radium or X rays, and more recently by iodine. The very definite advance made with iodine in the last few years can, in fact, be largely attributed to the introduction of methods which make it possible to follow accurately the course of the disease.

THE TEACHING OF TUBERCULOSIS.

THE differentiation of function in public health administration does not always make it easier to teach medicine to students. One by one diseases are being removed from the list of those which a general teaching hospital may treat in its wards, and are being relegated to the special hospital—often to State hospitals with no facilities for instruction. Tuberculosis is one of the latest and most conspicuous examples of this apparently inevitable trend of modern organisation. As the dispensary system develops, with its connecting links of sanatoriums and hospitals for surgical tuberculosis and advanced cases, fewer patients are treated at the general hospitals. It would be no exaggeration, indeed, to say that the newly qualified doctor has had little opportunity of studying the life-history of pulmonary tuberculosis, and although this disease is still one of the commonest causes of death in this country many men go out into general practice ill-equipped to coöperate in the comprehensive antituberculosis scheme which has been developed since the report of the Astor Committee.

Two recent handbooks for the student and practitioner form a useful contribution to this task of teaching the main outlines of pulmonary tuberculosis. The one, "Tuberculosis of the Lungs," [1] is a practical guide for general practitioners, written by Dr. H. Hyslop Thomson and Dr. A. P. Ford, who have charge of the tuberculosis scheme of Hertfordshire; the other, "Pulmonary Tuberculosis," [2] by Dr. G. T. Hebert, physician in charge of the Tuberculosis Department of St. Thomas's Hospital, comes from the experience of a teacher. The first is a condensed survey of the subject from historical summary to after-care and employment. It is orthodox and reasonable, and it omits nothing of vital importance, though it breaks no new ground. The practitioner is instructed in the administration of tuberculosis schemes and helped to visualise his own important position in them; chapters are devoted to diagnosis in general practice, domiciliary treatment, after-care and employment, prognosis—that most difficult of subjects—and the nursing of tuberculous patients, all of which are part of his daily life. The authors have managed to get a remarkable amount of information into the compass of a small handbook. It is a moot point, however, whether it might not have been better to let some of less important portions, such as the historical summary, go by the board, and to have given more space to subjects which harass the general practitioner—e.g., the care of the phthisic whom the sanatorium or hospital has sent home to die. Dr. Hebert's book is written from a different standpoint, that of the teacher who wishes to emphasise the main points in the clinical study of pulmonary tuberculosis. The examination of the patient, the study of his symptoms, the interpretation of the radiogram, and the description of special complications, such as hæmoptysis, pleurisy, and pneumothorax, all have the right emphasis laid upon them in the right place. Fibrosis of lungs, also, which so frequently confuses the beginner, is clearly described, whilst the chapter on physical signs contains tables and diagrams which we believe are quite new and original, and which should prove of great value to the student. One of the best chapters in the book is that on the evaluation of evidence. It would be difficult to exaggerate the importance of this subject, and Dr. Hebert's common-sense outlook, clear thinking, and experience have combined to make his treatment of it really brilliant.

Both these books, we believe, will find a place in the teaching of tuberculosis. They approach the subject from different angles, but they should help to focus attention on the real need which exists for the instruction of the student and the newly qualified graduate in an important subject.

LIVING CYTOLOGY.

A BEAUTIFULLY illustrated paper by the late Dr. T. S. P. Strangeways and Dr. R. G. Canti appears in the last number of the *Quarterly Journal of Microscopical Science* (1927, lxxi., 1). It describes the appearances which can be made out by skilful dark-ground illumination of living cells in tissue-cultures and the changes which are produced by flooding the specimen with various fixatives while under observation. The descriptions and figures are worth careful study. In brief, it was found that no cell-wall, nuclear membrane, or Golgi apparatus was visible—which is not, of course, to say that they were not there—nor were spindle fibres seen in cells in mitosis. On the other hand, the nucleus, nucleoli, mitochondria, fat globules, cytoplasmic granules, and pigment rods were quite distinct, and a lively account is given of the writhing of the mitochondria. All the fixatives tried produced more or less precipitation of fine granules in nucleoplasm and cytoplasm; except osmic acid, they all caused shrinkage of the cell, especially chromic acid; several reagents had a curious effect in causing discrete globules of fat to run together; anything containing acetic acid distorted or destroyed the mitochondria and an appropriate fixative brought the mitotic spindle into sight at once. Generally speaking, the old idea that osmic acid produces least change is confirmed, and there is a remarkable note that light dissolves cells which have been fixed in chromic mixtures. Altogether the paper is a very valuable contribution to the rationale of cytological methods.

ROCKEFELLER PUBLICATIONS.

VOL. LIX. of the collected reprints which are issued from time to time as Studies from the Rockefeller Institute for Medical Research is a portly book of 660 pages containing 50 papers and an index. The quality of the different items is as high as usual; some, perhaps, are rather dull and many are tantalisingly incomplete owing to the prevalent habit of publishing a number of small papers rather than waiting till such progress has been made as will justify a solid account which must often (though not always) be rather bulky. But we have learned to be confident that Dr. Simon Flexner will not allow very much that is only "fair to middling" to emerge under the auspices of the Institute which he controls. The range of subjects dealt with is very wide, as necessarily follows from the policy of the organisation in securing good brains and letting them go where they will. Looking down the table of contents, we are struck again by the fact that very little of the research is directly medical. Indeed, in the present volume there is but one clinical contribution (on the effect of digitalis on auricular premature contractions) from the hospital attached to the Institute, and of the others one of Dr. Noguchi's papers on Oroya fever is the least remote from practical work. Our know-

ledge of the foundations of medicine is outstripping its clinical applications. The truth is that exact laboratory work is much simpler than ward work of anything like equal precision. The really inferior part of the volume is the organisation of its production; the classification in the list of contents is bizarre and the index is useless. In these days of mass production good indexes are worth care.

A second publication emanating from the Institute gives an account of its constitution, organisation, and equipment, and illustrates the means by which the Studies are produced. The scientific staff numbers 100. We have also received from another branch of Mr. Rockefeller's benefactions, the Rockefeller Foundation, the seventh number of the accounts, which appear from time to time under Dr. R. M. Pearce's direction, of the fabric and equipment of buildings used for medical education. It contains an interesting and well-illustrated account of the new school of medicine and dentistry which was opened at Rochester, New York, last autumn. The most noticeable feature is the inclusion of the departments of anatomy, physiology, and biochemistry, as well as those of pathology and bacteriology, in the same building as the hospital wards. Unity of purpose and work is without doubt best achieved in this way, and many schools have been slow to realise that a separation in space which seems trivial may mean an isolation of interest. The detailed accounts of the various departments will be very useful to those who are occupied with new buildings. A good many of the rooms pictured seem to be rather badly lit, and the workers who appear in the photographs look preternaturally earnest and strenuous.

ANAPHYLAXIS AND URTICARIA.

THE conception that the cutaneous reaction known as urticaria might be a manifestation of the anaphylactic state was advanced by Wolff-Eisner soon after the peculiar phenomenon of anaphylaxis was first observed in animals. The theory has received much support, and it is generally acknowledged that although there is a wide difference between the condition of an animal which has been reinjected after an interval of ten days with some foreign protein and a patient suffering from urticaria, yet there is a relationship between the two states. A case jointly reported by Pasteur Vallery-Radot, P. A. Carrié, P. Blamoutier, and M. Laudat,[1] seems considerably to strengthen this view.

The patient was a woman, aged 28; after undergoing moderate exertion for a few minutes she not only suffered from a profuse urticarial rash but also showed signs of dyspnœa, vertigo, profound cardiovascular disturbances, and collapse—her condition closely resembling that of an animal suffering from true anaphylaxis. A detailed examination of the blood and cardiovascular system revealed a further similarity, for the patient was found to have leucopenia, moderate eosinophilia, fall of blood pressure, and albuminuria shortly after each attack. From the description given it does not appear that for any considerable time after an attack the patient experienced the protection which is observed in animals for at least ten days after anaphylactic shock.

Urticaria following muscular effort has been previously recorded on more than one occasion, and with the knowledge that an animal—and probably man—cannot (with the exception of the lens) be sensitised by its own tissues, the phenomenon is difficult to explain. The possibility that histamine released from the tissues is the exciting cause must be considered, for this substance is known to produce urticaria, and also a condition closely allied to anaphylactic shock, when injected into animals or man. Dr. Vallery-Radot and his collaborators regard their patient as one of a group "atteint d'instabilité colloidoplasmatique," in which at times physical effort may produce urticaria, asthma, migraine, or even shock. The case is of still further interest inasmuch as a cure was apparently achieved by two injections of sodium thiosulphate. It was found that the alkaline reserve of the blood was subnormal, and in view of this deficiency sodium bicarbonate was administered by the mouth. This raised the alkali to within normal limits, but did not prevent the attacks. The same salt given intravenously did, however, partly relieve the patient. On the assumption that the relief was in reality due to the desensitising power of sodium bicarbonate, and not to its influence on the alkalinity, the neutral salt, thiosulphate of soda, which is known to have similar desensitising power, was given intravenously on two occasions. Each injection was followed an hour later by vomiting, headache, and tremors, a condition which reminded the authors of the nitritoid crises which sometimes follow the injection of the arsenobenzol compounds. The patient was duly rewarded, however, for although she had suffered from these distressing attacks for a year and a half they now ceased. Apparently the shock produced by the injections of this neutral salt in some manner modified the unstable or allergic state of this patient, thereby enabling her to resume her customary habits without further inconvenience.

INTERNATIONAL OPHTHALMOLOGICAL CONGRESSES.

FOR two years an Anglo-American committee has been preparing the ground for a revival of the international ophthalmological congress held every four or five years before the war. The last step was to call a conference to frame the constitution, and the friendliness and unanimity which characterised last week's meeting at Scheveningen soon made it easy to achieve the common aim. The success of the conference (which we report in another column) must largely be attributed to the unbounded hospitality shown by the Dutch hosts. None of the delegates will readily forget the kindness of Prof. van der Hoeve and others who provided delightful opportunities for the delegates to meet one another, and no one who visited Scheveningen will voluntarily miss the congress to be held at Amsterdam in September, 1929. Meanwhile, ophthalmologists in all countries may well be grateful to those who worked hard to achieve these ends, and we note with especial pleasure the election of Mr. Treacher Collins as Hon. President of the International Council and of Mr. Leslie Paton as its treasurer.

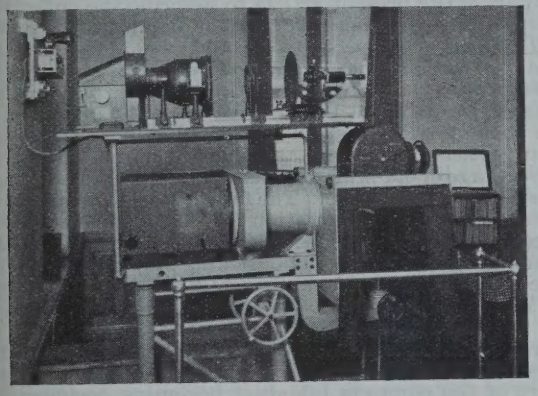
MEDICAL RESEARCH IN THE COLONIES.

A PROPOSAL for the establishment of a joint committee of the Colonial Office and the Medical Research Council was endorsed by the recent Colonial Office conference. The Secretary of State for the Colonies, in consultation with the Medical Research Council, has now appointed the Colonial Medical Research Committee with the following terms of reference: "To advise the Secretary of State and the Medical Research Council upon the initiation and promotion of medical research in the interests of the Colonial Empire; upon the recruitment and conditions of service of the necessary personnel; and upon the management and allocation of any funds available for these purposes." The Committee will also investigate proposals for the creation of a Colonial Medical Research Service and for the payment from a pool of grants to medical institutions which are considered to deserve the support of Colonial governments.

The Committee has been constituted as follows: The Right Hon. W. Ormsby-Gore, M.P. (chairman); Sir George Maxwell (deputy chairman); Members: The Secretary of the Medical Research Council, Sir Walter Fletcher; and the Chief Medical Adviser to the Secretary of State for the Colonies, Dr. A. T. Stanton, *ex officio*; Prof. J. W. W. Stephens; Sir Leonard Rogers; Dr. Andrew Balfour; Dr. Charles Todd; Dr. P. H. Manson-Bahr; and Dr. C. M. Wenyon.

THE NEW EPISCOPE AT THE ROYAL SOCIETY OF MEDICINE.

THE new Zeiss epidiascope—or episcope as it is called—which has been installed in the West Hall of the Royal Society of Medicine as part of a memorial to the late Sir John MacAlister, has a number of interesting features. Designed to project on the screen images of opaque objects, such as books, drawings, and flat specimens, as well as of objects in jars in a vertical position, it was found necessary to construct a revolving front to the apparatus. As this would, of course, give an inverted picture on the screen, when the plane mirror is in use, a special roof mirror was designed, both mirrors being housed together in a metal casing at the top of the revolving front. To change from one mirror to the other it is only necessary to move the small lever on the right of the apparatus. A 30-ampere arc lamp has been fitted with a specially worked



mirror, and to prevent any damage occurring to the specimens from the heat of the lamp a water-cooling chamber is interpolated between the lamp and the object stage. Mounted above the episcope is a table carrying two optical benches and a small 5-ampere arc lamp. This lamp is so constructed that it can be moved instantly from one bench to another. One optical bench is fitted with special condensing lenses provided with iris diaphragms, adjustable sole plate and microscope for the projection of microscopic objects; to obtain the desired size of picture on the screen a special eyepiece was designed. At the recent demonstration of the episcope to Fellows of the Society a picture of a microscopic object under a 1/12 inch oil-immersion objective was projected a distance of 32 feet, lighting and definition both being excellent—a great technical achievement. The second optical bench is fitted with large condensing and projection lenses, a double lantern slide carrier, and the other requisites for the projection of lantern slides of various sizes. The projection of large X ray plates is also carried out on this optical bench. The problem of projecting such large plates in a vertical position presented many difficulties, and was only solved after a long series of experiments. The instrument has been designed with interchangeable fittings, each having a little numbered celluloid disc inserted in the metal base, a corresponding disc being fitted to the optical bench showing the correct position. In scope and adaptability this episcope greatly exceeds anything hitherto used in this country; both the Society and Messrs. Carl Zeiss, of Jena, are to be congratulated on its installation.

RETIREMENT OF PROF. J. A. MACWILLIAM.—The Aberdeen University Court has received intimation from Prof. J. A. MacWilliam, M.D., F.R.S., that he is retiring from the Chair of the Institutes of Medicine (Physiology) in the University, which he has held for 41 years; a minute of the appreciation of Prof. MacWilliams's work has been passed by the University Court. The patronage of the chair is vested in the Crown.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXIII.—CHRONIC PANCREATITIS.

DURING the last few years the place taken by chronic pancreatitis as one of the common diseases of digestion has become more and more apparent, and its treatment has become a question of considerable importance. Chronic diseases of the pancreas may result in interference with the functions of the islands of Langerhans or with the alveoli. In the former case one of the types of diabetes may result, and in the latter the disturbance is mainly concerned with the external secretions of the organ. It is with this type of disease that the present article deals. Glycosuria is sometimes a transient sign in these cases, but it is seldom severe and only very rarely persists. There are two main types of chronic pancreatitis, catarrhal and chronic interstitial.

(1) *Catarrhal pancreatitis* is characterised by periodic attacks of nausea, vomiting, and diarrhœa, with bulky stools laden with undigested fat. The attack is nearly always heralded by a bout of shivering and a feeling of vague abdominal discomfort which may amount to definite epigastric pain, which is then generally associated with pain referred to the back beween the scapulæ. Catarrhal pancreatitis due to infection which may enter the main pancreatic duct from the common bile-duct or duodenum, or may be carried into the organ from the liver by lymphatic vessels.

(2) *Chronic interstitial pancreatitis* may be of three types, interlobular, interacinar, and a degenerate lipomatosis. The interlobular is the common variety, and the one principally associated with interference with the external secretion. The symptoms are less acute than with catarrhal pancreatitis. There is diminution rather than suppression of the external secretion; thus, diarrhœa and nausea are rare. On the other hand, there is marked interference with the digestion, particularly of fat and protein, and intestinal intoxication is pronounced. Flatulence is the prevailing symptom, but most of these patients suffer a good deal of pain in the form of an aching back. This form of pancreatitis is due to infection from the liver or gall-bladder, which is carried to the pancreas by the lymphatics.

Chronic pancreatitis always appears to be secondary to some other chronic inflammatory process in the abdomen. In the majority of cases this is a disease of the gall-bladder; sometimes the pylorus or duodenum are at fault, and occasionally the cause appears to be in the appendix. Wherever the primary focus, it must be remembered that the treatment of the pancreatitis can only be a part of the general treatment of the causative disease.

To remove the primary focus is an axiom of surgical treatment; here is a possible exception. No case of chronic pancreatitis is cured by cholecystectomy alone. Even after removal of the primary infecting focus, the diseased pancreas must be coaxed back to health by strict attention to diet, drainage, and drugs.

Diet.

This should be chosen with two main objects in view: (1) relieving the strain on pancreatic digestion; (2) limiting the amount of intestinal decomposition.

Carbohydrates.—The burden of carbohydrate digestion must, as far as possible, be thrown upon the saliva. Prolonged mastication of carbohydrate food is essential. Bread should be cut thin, toasted, and eaten cold. Potatoes and "milk puddings" should be avoided. Crisp carbohydrate breakfast foods having a maize basis are particularly to be recommended. They should be eaten in conjunction with, but not soaked in, fruit juice and a little cream. The cream inhibits the flow of gastric juice, and so prolongs the period of active ptyalin digestion within the stomach.

Fats.—Fat digestion is accomplished almost entirely through the medium of the lypolytic ferment contained in the pancreatic juice, assisted by the action of bile. The amount of fat in the diet must, therefore, be reduced to a minimum. Unsaponified fat clothes small particles of protein, and so renders them inaccessible to the action of digestive juices, and encourages putrefaction. Fat must be rigidly excluded from the protein meals. Pork, bacon, and all forms of fat meat are to be avoided. Duck, goose, and all water fowl are rich in fat, and must also be proscribed. Of the more common fish, salmon, eels, herrings (fresh or cured), red mullet, mackerel, and halibut contain

too much fat to allow of their being included in the diet. No fat must be used in cooking, so that fried food and all sorts of pastries are excluded. The only forms in which fat may be given are cream and butter. They must be used very sparingly, and given only with pure carbohydrate meals. Where there is jaundice or diarrhœa from catarrhal pancreatitis, fats are forbidden altogether.

Proteins.—The digestion of proteins is shared by pepsin, trypsin, and erepsin. The bulk of the work, however, is borne by the pancreatic secretion. Proteins should be given in a form, therefore, that will most easily be dealt with by the stomach and succus entericus. Meat may be taken sparingly once a day, and must be lightly cooked and preferably minced, so that the maximum amount of pepsin digestion may be obtained. Fish, except those mentioned under the paragraph on fats, may be substituted for meat in the single protein meal that is allowed each day. Eggs should not be taken. Raw egg is not digested at all by the stomach, and little by the succus entericus, so that, with the failure of pancreatic juice, they leave a large residue for bacterial decomposition, and, according to Dr. Langdon Brown, the relatively large amount of sulphur contained in them makes them more prone to putrefactive changes.

Fruits, green vegetables, and salads, except radishes, may be taken in moderation, but salad dressings containing fat and egg should be omitted, and cooked vegetables, particularly spinach, must be innocent of butter.

Beverages.—Milk, tea, beers and stout, and sparkling wines are to be avoided. Nothing should be drunk during meals except at dinner, when one glass of good, dry, white wine or a small whisky, which should not be "drowned," will aid the gastric digestion. No alcohol should be taken between meals.

Drainage.

Drainage in chronic pancreatitis is employed, first, to relieve congestion of the organ by evacuation of its mucus clogged ducts, and, secondly, in order to remove infected material from the neighbouring bile passages, and so to minimise the amount of reinfection of the pancreas. Drainage is obtained in two ways: by the use of the duodenal tube and by operation.

Drainage of the pancreatic ducts through the *duodenal tube* involves practice in the handling of the tube by the doctor, and considerable patience on the part of the subject. The method I use is that advocated by Lyon, with a rubber tube of about 2 mm. in diameter, with a wall sufficiently thick to resist atmospheric pressure, and having a perforated silver acorn, 1 cm. by 0·3 cm., at the distal extremity. I do not have markings on the tube, as I find that only by experience in the use of the method, or by the use of the X rays, can the exact position of the tube in the stomach or duodenum be determined.

After a fast of about 15 hours the patient is propped up in the sitting position, and the tube, lubricated with glycerine, is swallowed until the acorn is lying well within the gastric cavity. This is determined by the cessation of retching. The patient is allowed to remain in the sitting position for two or three minutes, and then is placed on the right side, with the foot of the bed slightly raised and the head resting on one pillow. By this manœuvre the weighted extremity of the tube is allowed to hang down in the stomach over the pylorus. A 20 c.cm. syringe is attached to the tube, and some of the stomach contents aspirated. They will be found to be copious in quantity and opalescent in appearance. The patient is told to swallow the tube about half inch at a time, with an interval of about a minute between each swallow. A little water in a feeding cup may be given to the patient to assist in swallowing; in the majority of cases this is unnecessary. With the progress of the tube through the stomach, repeated aspiration should be practised in order to determine the relative amount of gastric juice present. It is found that when the tube enters the pyloric vestibule the amount of gastric secretion obtained by aspiration is only 4 to 5 c.cm. at a time. Swallowing the tube must then proceed very slowly, or it is apt to become curled up in the stomach. When the acorn end of the tube first touches the pylorus there is always a reflex attack of retching. This may be very short, only one descent of the diaphragm being noted. A careful watch should be kept, or this will probably be missed. No further attempt should be made to swallow the tube until a final and much more emphatic heave demonstrates the passage through the pylorus; now gentle traction on the tube will indicate the fact that the distal part is gripped by the pylorus. Further traction on the tube will start retching by pressure of the acorn on the distal side of the pylorus. Aspiration generally is unsuccessful in producing any fluid, but occasionally a little thick glary mucus can be extracted from the duodenum. The tube is now slowly swallowed for about three inches, until its extremity becomes approximately over the ampulla of Vater.

The patient may now turn over and lie on the back in a more comfortable position; the head may be raised if desired. A solution of 25 per cent. magnesium sulphate is used in the majority of cases to stimulate the flow of bile and pancreatic juice. A solution of peptone is often more active than magnesium sulphate in stimulating a flow of pancreatic juice, but the latter has the advantage of being cheap and readily obtainable. After the injection of about 40 c.cm. of the solution into the duodenum, repeated aspirations with the 20 c.cm. syringe are made, the plunger is withdrawn and pushed back, so that no fluid is actually removed from the duodenum. From five to ten minutes elapse before a change is noted, and then the solution becomes tinged with yellow. The colour of the fluid will get gradually deeper as the proportion of bile to magnesium sulphate solution increases. During the next three-quarters of an hour the duodenal contents must be slowly removed by aspiration, and it may be found necessary to repeat the injection of magnesium sulphate into the duodenum two or three times. It is no part of the present article to describe the collection of specimens of pancreatic fluid for diagnostic purposes.

Drainage by operation should be done at the time of the primary operation for dealing with the infecting focus from which the chronic pancreatitis arises. In the great majority of cases the operation is for cholecystitis complicated by gall-stones. If chronic pancreatitis be present, as indeed it is in a very large percentage of old-standing cases, drainage of the biliary passages is imperative. The failure to relieve digestive symptoms by the operation of cholecystectomy for treatment of gall-stones is generally due—this is the essential point—to the overlooking of pancreatitis and the failure to provide and maintain adequate drainage.

Much may be said of the relative merits of drainage of the biliary system through the gall-bladder or through the common bile-duct. Where there is any possibility of the ampulla of Vater or the terminal part of the common bile-duct becoming occluded by pressure of a sclerosing pancreatitis or other cause, the gall-bladder must be preserved, as it may be necessary ultimately to resort to cholecystoduodenostomy; but where there is advanced inflammatory disease of the gall-bladder it is better to remove the viscus and drain the common bile-duct. Draining must be maintained for several weeks. Where pain is a prominent feature of chronic pancreatitis, relief may be obtained by incising the peritoneum on the antero-superior surface of the pancreas.

Drugs.

Drugs serve two purposes. They may disinfect the pancreatic ducts after being secreted by that organ, or they may be used to control intestinal putrefaction. Sodium salicylate and aspirin are the only pancreatic disinfectants that appear to be of much value. I am indebted to Dr. Victor Schektor, of Boulogne, for the following prescription. Take the juice of four lemons in a large jug. Add sodium salicylate 20 gr., and sodium bicarbonate 30 gr. When the effervescence has subsided, add one bottle of Vichy water. Stir well, and drink a glass full at a time, consuming the whole quantity in 24 hours.

For the control of intestinal putrefaction two drugs of particular merit are oil of cloves, which should be prescribed in a pill, and calomel taken in small doses.

For those whose means allow, a prolonged course of treatment at a spa is generally beneficial. Little benefit is derived in these cases from treatment by dried pancreas or pancreatic extract. In extreme cases food may be prepared partially digested with pancreatic extract, but it is very unpleasant to take.

The Outlook.

The treatment of chronic pancreatitis calls for a considerable exercise of patience both on the part of the doctor and the patient. But no case should be despaired of, and although in the more advanced stages of the disease cure seems to be unobtainable, yet very great relief of symptoms may be confidently expected.

H. E. GRIFFITHS, M.S. Lond., F.R.C.S. Eng.,
Surgeon, Albert Dock Hospital.

Special Articles.

EMANCIPATORS.*

BY HARVEY CUSHING, C.B., F.R.C.S.,
PROFESSOR OF SURGERY, HARVARD MEDICAL SCHOOL.

IT has been given to few so to identify themselves with great benefactions to human-kind that the bare mention of their names will for ever suggest equally the man and his legacy. We may celebrate the discovery of anæsthesia as a great boon, with disputed remembrance of those who made it possible; or we may remember a name like that of Pinel and recall, some of us but vaguely, what it was he did for humanity's sake.

Rarely is it safe to prophesy any durability of recognition, whatsoever the accomplishment. Fame that is contemporary, fame that for a time endures, and fame that actually accumulates differ in quality as differ the flash of a meteor, the glow of a comet, the permanence of a fixed star. Only when the contemplation of both the man and his achievement truly inspires and ennobles us will they remain indivisible, to be praised by the people for time everlasting.

On a May morning a few weeks ago, with the depth of emotion the spot engenders, I stood at the portal of the Lincoln Memorial in Washington looking upon that marvellous seated figure of the Emancipator there enshrined. And as I read again those familiar phrases spoken at Gettysburg, there came to mind how comparable were he and Lister in their service to the proposition that all men are created equal. Lister freed man from the shackles of sepsis; Lincoln a race from those of slavery. Yet how different the men, their medium of service, and the manner by which the seemingly inevitable was thrust upon them.

Who have made the greatest gifts to their fellow-man? Those who have left an idea that has supplied, like the utterances of Christ, what minds have yearned for? Those who have added to his physical comforts and have found ways to lessen hunger and want? Those who have added to his conveniences and devised means to lighten his labour? Those who have, like Lincoln, freed him from bondage, and, like Lister, released him from the horror of suppuration? One answer certainly can be made: that only when the gift requires great self-denial, and only if the giver be one that walketh uprightly and worketh righteousness and speaketh the truth in his heart, will he, like St. Francis, come to be canonised and for ever blessed.

Often when issues are critical, circumstances so combine as to bring the right man, at the right time, to the right place. But rarely is an individual so caught up in the vortex of a revolution in thought as unmistakably to be at its very centre. It is idle to speculate whether the opportunity more often makes the man, as was perhaps true of Lincoln; or the man the opportunity, as was more apparently the case with Lister. All that matters is that the conjunction should take place. The opportunity of doing something of lasting benefit to our kind doubtless lies before us all. Yet, even have we the imagination to realise it, we want the courage to grapple with it, the tenacity to hold it, the persuasiveness and unselfishness which can alone make converts and disciples.

Whereas circumstances pitchforked Lincoln into his position of responsibility, Lister, horrified at the condition in which he found surgery, deliberately elected to crusade against the most serious obstacle in the way of its advance. Were these men accidental or inevitable? Suppose they had been born into the world 50 years earlier or 50 years later, would they have been unknown and unnamed? Would their particular form of genius have found an outlet for its expression at any place and time? Or were they victims of circumstance, each in his different sphere, singled out by the finger of destiny for a significant rôle which some other might well enough have filled? Was it mere chance that the anti-slavery movement came to be focused on Lincoln? Did Lister happen to make himself the focal point of the movement to banish sepsis merely because Pasteur's studies of fermentation gave the clue, and because the science of bacteriology, already conceived by him, was about to be born to smooth his path?

What preparation had either of these two? An obscure, uncouth, backwoods lawyer, the very product of the soil, Lincoln was suddenly by God's will lifted to an eminence where, surrounded by hostility and innuendo, he must shoulder burdens and make decisions affecting the permanency not only of a nation but of the institution of slavery as well. In Lister's case, what preparation? An utterly different background, to be sure, yet also a sensitive man to whom strife was hateful, he too was drawn by God's will into a position where, faced by opposition and misrepresentation, he must make a fight for the truth. And why? Simply because he had set out, innocently enough, to answer questions. Why does the pupil contract? Why does the blood coagulate? and later: Why do wounds fester? To this well-hidden secret he found an answer in which others, to whom lives were entrusted, must be made to believe.

We may well doubt whether blind fortune could have lifted from the crowd any more practical, humane, and earnest men, equally far removed from motives of self-interest, who could have filled, as they did, their difficult and lonely places. What was to be done must be done largely single-handed, for when numbers are concerned in mighty decisions it is a matter of uncertainty whether they will add to the confidence or the discouragement of him who must lead at any cost. Faith they had, soon conviction, and ere long experience. "The only faith," it has been said, "that wears well and holds its colour in all weathers is that which is woven of conviction and set with the sharp mordant of experience." Both faced situations without precedent and arrived over untried ways through the process of reasoning and experiment—one that a nation's life might not be lost, in conducting a war of principle, for want of a moral hold on itself; the other that the lives of countless people, irrespective of nationality, might not be sacrificed because of scepticism and ridicule.

Exceedingly little was the encouragement received from their professional brethren. Belief in Lincoln rested with the common people; it was the students who gave testimony to Lister when others doubted. As one met a hostile neutrality abroad, so did the other at home. But the more they were tried, the stronger they became; for both had that sweet reasonableness of disposition which is not embittered by hostility, and each the honesty to admit whatever of truth there might be in adverse opinion. The cautious but steady advance of Lincoln's policy during the war and of Lister's experiments during his patient struggles to get at the truth left a well-paved road behind them along which anyone, not blind, could follow and be convinced.

Lincoln was spared much of what Lister endured. Had Lister possibly been the victim himself, as other surgeons have been, of an accidental wound infection after he had made his great demonstration, he too might have been enrolled as a martyr and have escaped the trials and humiliations to which he was long subjected. An awkward civilian during times of great military achievement, Lincoln has left behind him the memory of a grace higher than that of mere breeding, a fame beyond that of any conqueror. Lister was to the manner born; yet he also, so strong and persuasive is honest manliness, has left the memory of that nobility of soul which makes him kin to all mankind.

*An Address delivered at the Lister Centenary Celebration at Edinburgh on July 20th.

One for an ideal; the other for an idea. One by proclamation; the other by demonstration. To establish the ideal took countless lives. Because of the idea more lives are saved each year than were lost in that prolonged civil war. But it was Lincoln who at the time of trial put into words for a people what Lister for a profession might have said with little change—as a dedication for us the living to the great task remaining before us:—

With malice toward none, with charity for all, with firmness in the truth as God gives us to see the truth, let us strive on to finish the work we are in; to bind up the people's wounds, to care for him who shall have borne the battle, and for his widow, and his orphan—to do all which may achieve and cherish a just and lasting peace among ourselves and with all nations.

The act on which Lincoln's life centres itself is not that for which an adoring nation has put a halo round his memory. Rather have a people, once divided, come to look upon him as expressing what they would wish to have represent them before the world. He thereby has become a symbol from which his countrymen reap a harvest of precious associations. So may our profession reap from Lister's life something far more precious than pride in his accomplishment and the satisfaction of claiming him as our own, that spiritual harvest which comes from the example of an unblemished character, for kindness, meekness, and comfort were in his tongue. Though lives die, the life is not dead; and the memory of lives such as these will be for ever shared, not by a profession alone, not by a nation alone, but by the whole brotherhood of men.

INTERNATIONAL OPHTHALMOLOGICAL CONGRESSES.

THE Convention of English-speaking Ophthalmologists, at a meeting held in London in 1925, asked its President, Mr. Treacher Collins, to nominate a small committee, whose function it would be to try to bring about a renewal of the periodical international ophthalmological congresses which, before the war, were held every fourth or fifth year. Mr. Collins nominated Dr. Edward Jackson (Denver), Dr. George de Schweinitz (Philadelphia), Sir John Parsons and Mr. Leslie Paton (London), as members of this committee, and himself acted as its convenor. The work of the committee during the last two years resulted in the calling of a conference at Scheveningen last week from July 12th–15th, which was attended by 48 delegates, representing 25 different nationalities. Of these delegates, one came from Chili, Dr. Thierry; two from the Argentine, Dr. Arganaraz and Dr. Demaria; two from Japan, Prof. Hata and Lieut.-Comdr. Tagawa; two from the United States, Dr. de Schweinitz and Dr. Parker; and two from Egypt, Dr. Meyerhoff and Dr. Riad. All the principal European nations except Russia, Turkey, and Greece were represented.

Much of the great success of the conference was due to the hospitality and forethought of the Dutch hosts, Prof. van der Hoeve (Leiden), Prof. Rochat (Groningen), President of the Netherlands Ophthalmological Society, and Dr. Marx (Leiden).

On Tuesday, July 12th, a preliminary meeting was held in the Orange Hotel, Scheveningen, at which Prof. Rochat welcomed the delegates equally eloquently in English, French, German, and Italian. Mr. Collins explained the circumstances which had led up to the summoning of the conference, and gave a short history of the previous international congresses. He then moved that Prof. van der Hoeve should take the chair. Mr. Leslie Paton (London), Dr. Marx (Leiden), and Dr. Pflüger (Berne) were nominated to act as secretaries of the conference. The principal motion—"that the International Congress of Ophthalmology be reconstituted"—was carried by acclamation, and committees were appointed to consider: (*a*) rules and by-laws; (*b*) the place and date of the first meeting of the new Congress, and the subjects for discussion; (*c*) finance; and (*d*) the questions of international ophthalmological importance that should be remitted to the Council for discussion.

On the evening of Tuesday the Anglo-American Convening Committee entertained the delegates to dinner at the Palace Hotel. On Wednesday the committees met in the morning, and in the afternoon members of the conference were the guests of Prof. van der Hoeve in an excursion by car and steamer to Leiden and the lake district in the neighbourhood. In the evening, Mr. and Mrs. van den Bergh gave a dinner and a garden party in their beautiful garden at Wassenaar near The Hague.

Decisions of the Congress.

On Thursday morning the reports of the committees were received. Invitations had been received from Denmark, Egypt, and Holland for the first Congress, and from Spain for the second Congress. It was unanimously decided that the first Congress should be held at Amsterdam in September, 1929. The new rules and by-laws were unanimously adopted by the conference.

The subscription was fixed at £2 sterling, or an equivalent sum, for Members, and £1 for Associates.

Apart from the expenses of the Congress itself, a fund would be required to meet the expenses of the International Council, to hold office in the period intervening between the Congresses. Already a certain amount of expense had been incurred in preparation for this conference. To meet these and other Council expenditure it was resolved to ask for voluntary subscriptions of not more than £5, or less than £2, from ophthalmological or other medical societies, or from individuals. Any society subscribing will be entitled to receive a copy of the Transactions of the Congress for its library. In this way it is hoped to secure a sum sufficient to meet the expenses of the Council other than those directly connected with the Congress.

The management and finances of the Congress itself will be controlled by a national committee, elected by the ophthalmologists of the country in which the Congress is to be held, and working in conjunction with the International Council.

The Council was asked to decide on the subjects for discussion, both at the Congress and by special committees to be appointed by the Council.

An International Council was appointed, to hold office until the Congress of 1929. It consisted of Prof. van der Hoeve (Netherlands), chairman; Prof. Lundsgaard (Denmark), vice-chairman; Mr. Leslie Paton (Great Britain), treasurer; Mr. Marx (Netherlands), secretary; Prof. Axenfeld (Germany); Dr. Byers (Canada); Prof. Coppez (Belgium); Prof. Marquez (Spain); Prof. Meller (Austria); Dr. Morax (France); Prof. Ovio (Italy); and Dr. de Schweinitz (United States). As the concluding act of the conference, Mr. E. Treacher Collins was elected Honorary President of the International Council by universal acclamation, as a tribute to the work he had done towards ensuring the success of the conference and the future of international ophthalmology.

After the end of the formal business of the Congress the delegates were taken by cars to Nordwyk-on-Sea, where they were entertained to lunch by Prof. van der Hoeve, whose health was proposed in eloquent Latin by Prof. Ask, backed up in English by Dr. de Schweinitz, in German by Geh. Prof. Axenfeld, in English by Prof. Arganaraz, in Italian by Prof. Ovio, and in French by Dr. Velez. After lunch the delegates visited the palatial new ophthalmic clinic at Leiden and looked with envy on the spacious rooms and accommodation provided there for ophthalmological work.

COVENTRY HOSPITAL.—Mr. W. R. Morris has given the cheque for £15,000 to the Coventry and Warwickshire Hospital which he promised on condition that the hospital carnival committee raised over £5000 by its efforts.

NEW WAR MEMORIAL HOSPITAL AT SELBY.—Viscount Lascelles has promised to open the new Memorial Hospital at Selby on Oct. 4th. Princess Mary laid the foundation-stone of the new building, which is costing £16,000, last autumn.

BRITISH MEDICAL ASSOCIATION.

REPRESENTATIVE MEETING, EDINBURGH.

THE annual Representative Meeting opened in the McEwan Hall, Edinburgh, on Friday, July 15th, under the chairmanship of Dr. H. B. BRACKENBURY. After some formal business, the Chairman recalled the fact that the patron of the Association, H.M. the King, was in residence at Holyrood and a message of humble and loyal greeting was sent.

Lieut.-Colonel F. O'Kinealy, I.M.S. (retd.), was appointed the representative of the I.M.S. on the Council for 1927–30; Dr. F. G. Thomson, immediate past-President, was elected a vice-President of the Association, and it was agreed that Sir Ewen Maclean be elected President for 1928–29. In thanking the meeting, Sir Ewen Maclean recalled the fact that the Representative Body had had its birth in Wales and said he believed he was the first President who had ever previously held the office of chairman of the Representative Body.

It was agreed that the annual meeting for 1929 should be held in Manchester and for 1930 in Winnipeg, Canada, and that a book of signatures should be instituted to form a permanent record of membership of the Representative Body.

In moving the adoption of the annual report (preliminary), Sir ROBERT BOLAM, chairman of Council, remarked that although the Association as a whole had been unable to take steps towards forming a Jenner Museum at Phipps Cottage, offered by Lork Berkeley for that purpose, nevertheless local members were taking action in the matter.

Locum Bureaux.

In 1925 the Representative Body instructed Council to form a bureau for the provision of locum tenents and assistants. Sir Robert Bolam reported that it was not practicable for the Association to run such a bureau, but an arrangement had been entered into with the Scholastic, Clerical, and Medical Association, Limited, whereby the British Medical Association held a half interest in the agency's shares and one half of the board of directors were to be members of the Association. Thus influence would be exercised to ensure that the work of the agency is conducted on lines consonant with the policy of the B.M.A. For the duration of this agreement the agency was to be allowed to use the title "British Medical Bureau." There would be slight advantages for B.M.A. members, but the agency would continue to be run on business lines.

A motion from Gateshead, protesting at this action of the Council without further reference to the Representative Body, was withdrawn after discussion.

Civic Welcome.

The Lord Provost of Edinburgh (Mr. ALEXANDER STEVENSON), with the President-Elect of the Association, Sir ROBERT PHILIP, then entered the hall. The Lord Provost, welcoming the meeting to his city, referred to the especial regard and pride which the municipality had always felt for its medical faculty and also to the coincidence of the Association's visit with the centenary of Lord Lister. Dr. BRACKENBURY briefly replied.

Sir ROBERT BOLAM announced that Mr. W. E. Hempson, solicitor to the Association for 27 years, had conveyed his resignation to the Council. He proposed that Mr. Hempson be elected an honorary member of the Association. This was carried amidst loud applause.

Finance and Organisation.

The Treasurer, Mr. BISHOP HARMAN, reported that there was an exceptionally good balance sheet and a large increase of membership, the year's surplus being twice what had been anticipated in their budget.

Dr. MORTON MACKENZIE, proposing the adoption of the annual report under "Organisation," outlined the proposed scheme for the formation of groups within the Association. It had been found, he said, that certain members engaged in special practice could not get their views and particular difficulties adequately expressed through the ordinary machinery of the Association. In such cases it was suggested that the Council should have power to form a group. The group meeting would appoint a committee of six which might meet twice a year at the head office and at other times by consent of the Chairman of Council; their expenses would be paid in the usual way. The findings of this committee would be placed before the appropriate standing committee. If the latter agreed with them it would incorporate them in its own recommendations to Council, but in any case the findings of the group committee must be placed before the Council, which might invite a representative of the group to attend its deliberations on the matter. The annual meeting of the group was to be held at the time and place of the annual meeting of the Association, in order that the members might realise that they were a part of the B.M.A.

The Harrogate division put forward two amendments which, after some discussion and verbal emendation, were accepted by the Chairman of the organisation committee. They read:

(1) That the Council be asked to consider that, subject to the approval of Council, the Executive Committee of the group should define the qualification for membership of the group, and (2) that the annual group meetings should be held, if the time of the B.M.A. annual meeting were found inconvenient, and with the approval of the Council, at such other time as the Executive Committee of the group may think desirable.

The formation of groups was opposed by Dr. J. MIDDLETON MARTIN, of Gloucester.

Dr. R. GORDON (Bath) said that the Association of Spa Practitioners had been opposed by several B.M.A. members, who had only consented to its formation when they found that the existing organisation could not meet their need and when they had been assured that the Council hoped soon to evolve a scheme whereby the group could be taken under the wing of the Association.

Mr. BISHOP HARMAN said that the existing machinery was not elastic enough; some years ago a number of ophthalmic surgeons had been obliged to band themselves, and pathologists had similar difficulties. The proposed expansion would not affect the fundamental constitution.

Sir ROBERT BOLAM assured the meeting that it need have no fears for the constitution of the Association, which was being carefully guarded.

The motion was carried.

Dr. MORTON MACKENZIE then reported that there had been an increase of 1800 in the membership during the year past, including 700 new members from overseas, whence came most encouraging reports. The South African organisation was now established and working well; all that the members there had wanted had been achieved. There were now 50 overseas branches. At home the principal activity had been in the direction of increased local scientific work. The lecture on Cancer by Sir Berkeley Moynihan in the spring had convinced them that the occasional provision of such a lecture, after careful preparation and with a kind press, was a valuable factor in convincing the public that the Association had the public health at heart. Excellent recruiting work had been done among the newly qualified, especially in Glasgow, where 90–95 per cent. often joined up; last May 100 per cent. of those qualifying became members.

Dr. J. B. MILLER brought forward a proposal by Lanarkshire:

That the Council be instructed to consider the taking of such steps as are necessary to secure that members attending meetings of Council and Central Committees be paid reasonable out-of-pocket expenses in addition to railway fares.

He pointed out that although there had not been, and probably would not be, any difficulty in obtaining

the services of the best people to do the work of the Association, yet many of them gave those services at considerable personal loss. Members who travelled backwards and forwards daily were allowed double or triple fare, but it would be much better for them to spend that allowance on a quiet bed in town. He suggested a scale similar to that allowed for civil servants absent from their homes on duty.

Dr. PETER MACDONALD (York) supported the motion, saying that the time had come to consider this matter very earnestly. Those who did the work of the Association had to be selected on the worst basis of all—a pecuniary one—and the best man was sometimes excluded. The matter would be costly, but he wished the treasurer would give up trying to think as a Scot, as the efficiency of the work would be greatly enhanced.

Mr. BISHOP HARMAN opposed the motion on the ground that it would be only logical to include the whole Representative Body, which would mean an increase of nearly 100 per cent. on the present cost of meetings. The finances would not bear this. In the past, local efforts had met such financial difficulties as had arisen. He deprecated the tendency to require equivalents for work done and gloried in voluntary work.

Dr. MILLER contrasted attendance at the Representative Meeting, in fine weather and pleasant surroundings, with journeying to London in a November fog to serve on a central committee. His motion was carried.

New Buildings.

After lunch the meeting was resumed in the anatomical theatre, where Sir ROBERT BOLAM (chairman of the building committee) gave a lantern demonstration of proposed extensions to the present house in Tavistock-square. The Association, he said, was already bound to take over the houses adjacent to its strip of private road, an area of 11,240 square feet, at a cost of £12,000. It now had the opportunity to acquire further blocks on either side of these, the northern one falling in in 1934 at a cost of £90,000 and the southern in 1938 at a price of £100,000. By securing the long lease of these two additional blocks the Association could erect a magnificient building, completed about 1940, at a total cost of £310,000. The finances of the Association would enable this to be done without great difficulty and without interfering with the present activities and reasonable expansion of other work. Nor would there be any need for borrowing, for their credit was good enough to cover the whole expenditure if necessary. He spoke eloquently of the importance of taking the long view in this matter, of the asset which would be left to the profession by the generation which undertook such an outlay and of the power of money, power of position, and enhanced prestige at home and abroad that such a home would assure. He was supported by the treasurer, the solicitor, the three oldest members present, and by a number of other speakers. All paid enthusiastic tribute to Sir Robert Bolam's capability, courage, and statesmanship in conceiving the scheme, carrying it through against much preliminary opposition and presenting it so lucidly to the meeting. After two or three questions had been asked and answered the report of Council under "Building" was carried unanimously and with applause.

The British Medical Journal.

Dr. J. A. MACDONALD, proposing the adoption of the annual report of Council under "Journal," reviewed the work and progress of the *British Medical Journal*. There had been a steady increase in circulation and in income from advertisements. The Association had also published the *Archives of Disease in Childhood* and the *Journal of Neurology and Psychopathology*.

Dr. L. A. PARRY moved, on behalf of Brighton:

That, whilst recognising the responsibility for all that appears in the *British Medical Journal*, and its supplement, as defined in Article 38 of the Association, the Representative Body is of opinion that those periodicals should be open to communications from any members commenting, favourably or otherwise, either on the policy of the Association in regard to the medical and allied sciences or on a communication inserted by a department of the Association.

He related a personal experience in this connexion and protested against the restriction of free discussion on controversial subjects.

Dr. C. O. HAWTHORNE said that the principle involved was the position of the Editor. No capable man could accept a situation in which he might be called upon to receive 30,000 letters, on any subject, each of them having the right to appear within the columns of his journal. The Brighton motion took away from the Editor his responsibility for what appeared in the journal and left him only the question: Is this a communication from one of my 30,000 masters and necessarily, therefore, to be inserted? There was no halfway house between trusting an editor and dismissing him.

Dr. J. A. MACDONALD said that it was not correct to say that a member might not use the columns of the journal to criticise one of the committees. In this case it was the action of the Council, which had given instructions for a strong propaganda movement, which the letter would have weakened.

Sir ROBERT BOLAM said that the only mistake the Editor had made was in attempting to give a reason for refusing Dr. Parry's letter. Dr. Parry would see that it was impossible to conduct a scientific journal on the lines laid down in his resolution.

The motion was lost.

A motion by Plymouth, asking that local meetings should be reported more fully and conspicuously, was lost.

Edinburgh and Leith brought forward two motions for the improvement of the journal. The first, asking that the proceedings of the annual meeting should be printed in one volume, was opposed by the Chairman of the committee on the grounds of impracticability and was lost. The second, requesting the Council to consider the possibility of improving illustrations was answered by Dr. Macdonald in a careful statement of the technicalities and cost of reproducing pictures and was withdrawn.

Medical Ethics.

In proposing the adoption of the report of Council under "Ethics," Dr. LYNDON brought forward the recommendation—

That the Representative Body considers it undesirable that there should be inserted in the medical press or in other publications primarily intended for the medical profession any advertisement of a therapeutic institution which includes any laudatory statement of the form of treatment given or the private address or the consulting-rooms or hours of a member of the medical staff; but that there is no objection to the name and qualifications of medical officers of the institution being given.

He reminded the meeting that in 1924 the Representative Body had decided that the advertisements of institutions professing to provide medical advice and treatment, together with the name of the resident and visiting medical officers, were unobjectionable. It had since been found that some of these advertisements were open to objection in that they contained laudatory statements of the treatment offered and the private addresses and consulting hours of medical officers.

Dr. F. RADCLIFFE (Oldham) drew attention to the effects of this resolution on institutions such as the Cheadle Royal Asylum, which published an advertisement giving the hours and place at which patients or relatives might consult the medical officer in Manchester. Questions elicited the fact that in the case the doctor was not seeing private patients for his own gain. There was some discussion, in which Mr. McAdam Eccles and Dr. R. Langdon Down took part. There was general agreement that advertisements in which the particulars were inserted for the doctor's private gain were undesirable, the difficulty, as Sir Robert Bolam pointed out, being to adjudicate in any instance. Finally it was agreed on the motion of Dr. F. Radcliffe and Dr. J. D'Ewart

(Manchester) to amend the resolution by substituting the words :

"or the address, or the consulting-rooms, or the hours of a member of the medical staff at which he sees private patients" for the words "or the private address or the consulting-rooms or hours of a member of the medical staff."

Dr. S. P. KAPADIA (Bombay) made an eloquent appeal to the meeting to stiffen the standard of medical ethics by refusing to allow any reference to the medical officer at all. His amendment was seconded by Dr. D. ROXBURGH (Marylebone), but was not carried.

Dr. LYNDON, moving the remainder of the report, remarked that it had not been found desirable to draw up an ethical code, other than that laid down in the "Handbook for the Newly Qualified." Nor did the Council consider necessary any further extension of the existing machinery for dealing with professional disputes.

Dr. C. H. MILBURN (Harrogate) deplored the number and character of signed contributions from medical men in the press and thought the best way of dealing with abuses was to educate the younger members. He proposed on behalf of his division, and carried, a resolution :

That the Council be instructed to consider any further steps which may be thought necessary for the instruction of senior students or newly qualified practitioners in medical ethics.

The proposal was supported by Dr. J. F. WALKER (Southend).—Sir ROBERT BOLAM and Dr. LYNDEN reminded the meeting that much was already being done in the medical schools, both by example and by precept. The General Medical Council had satisfied itself that the attention of authorities had been drawn to the need for such instruction and had advised the teaching bodies in 1922 that students should be grounded in the subject.

SATURDAY, JULY 16TH.

In the absence of the chairman, owing to indisposition, the chair was taken by the deputy chairman, Dr. C. O. HAWTHORNE. While he, as chairman of the Science Committee, was dealing with that portion of the annual report, Dr. WALLACE HENRY, immediate past-chairman, presided.

Pathological Institutes and Reports.

Dr. HAWTHORNE said that as a result of complaints from members in private practice as pathologists that they were being unfairly treated, the Council had carefully considered the position of advertisements of pathological institutes and of commercial and public health laboratories. The Council had adopted the following general propositions :

(*a*) That in the interests of medicine and of medical practice the status and professional values of the private practitioner of pathology should be more generally recognised ;

(*b*) That the practice of clinical pathology should be conducted in accordance with the professional customs and ethical principles that govern other specialised departments of medical practice ;

(*c*) That so far as possible, and this especially in difficult and obscure cases, the pathologist and the practitioner in charge of the patient should meet in consultation ;

(*d*) That a practitioner engaged in private practice as a pathologist is at liberty to notify the fact, together with his professional address, to medical practitioners within the area of his practice ;

(*e*) That in no circumstances should a pathological report be furnished to any person other than a qualified medical practitioner.

Later on in the meeting Dr. PARRY moved, for Brighton, an amendment, accepted by the chairman of the Science Committee, to insert words making it clear that dental practitioners are included throughout. It had been decided, said Dr. Hawthorne, that the Association should discourage, or at least abstain, from encouraging laboratories governed by purely commercial and advertising ambitions, partly because of the unfair competition they set up with the private pathologist who could not and had no wish to advertise, and partly because there seemed no logical end to the departments which might be set up as side lines to a commercial firm. If such firms ran clinical laboratories and gave reports on pathological material, why should they not run X ray departments, or, indeed, why not provide a consulting surgeon or physician to furnish clinical reports ? The Council was convinced that the status and professional values of the private practitioner of pathology should be more generally recognised. Their attitude was expressed in four recommendations, some of which aroused considerable interest and discussion. The first was :

That the Representative Body disapproves of the establishment by trading firms of laboratories as subsidiary enterprises for the purpose of offering pathological examinations and reports on individual cases, and advises members of the Association to avoid any association with such enterprises.

This was carried unanimously. The second was :

That in the opinion of the Representative Body all institutions undertaking pathological examinations and reports should include in any intimation made to the profession the name of the registered medical practitioner in charge of the laboratory, and that each report issued from the laboratory should be guaranteed by the personal signature in writing either of this practitioner or of some other registered medical practitioner approved by him.

This, Dr. Hawthorne explained, was to put a stop to the "communal guarantee" of institutions and to insist on the personal responsibility of the individual reporting on a specimen. It was carried.

The third recommendation stated :

That in the opinion of the Representative Body public health authorities should neither provide for pathological examinations nor furnish pathological reports on individual cases, except (i) in cases which directly involve questions of public health, or (ii) where provision is made for such reports by statutory right, or (iii) when the patient is stated by the practitioner to be, in his opinion, unable to pay a fee.

Dr. L. A. PARRY, proposed but failed to carry an amendment by Brighton to delete the third paragraph of this resolution ; he said that once it was admitted that public authorities should investigate pathological conditions they came into competition with private pathologists. There was ample provision for poorer patients.

Dr. HAWTHORNE objected that time might be an essential element in an examination, and said it was a mistake to be too scrupulous about the methods by which the required information was obtained in such cases.

Dr. C. E. S. FLEMMING (Salisbury) said that the resolution would involve the setting up of another laboratory for each area where there was only a public health laboratory in existence. This duplication would imperil the work. In neither of the two small institutions would there be such good equipment or such wide and varied experience as in the one big one, and work would be taken away from private pathologists.

Dr. G. CLARK TROTTER (City) strongly supported the motion. He pointed out that it was not incumbent on the public health authority to do these examinations. It was for the medical officer of health to decide whether they were in the interests of the public health or not. Indiscriminate swabbing of throats might be performed as a placebo, or among contacts from whom nothing could be learned. Often it was more valuable to do a pathogenicity test on throat swabbings than a culture.

Dr. H. S. BEADLES (Romford) looked forward to the day when the pathological laboratory would be open to all cases ; at present the work in public health institutions was limited to diphtheria, syphilis, typhoid, and tuberculosis, although some of them would do other investigations at a fee which was considerably lower than that of the private pathologist. He knew of only one laboratory where it was possible legitimately to get investigations made for panel patients ; this was in a town where the work was done municipally for everybody.

Dr. J. STEVENS (Edinburgh) protested at Dr. Clark Trotter's claim to decide without seeing a case whether the investigation required by the doctor in charge were necessary or not.

Dr. S. C. DYKE (S. Staffs) urged the absolute necessity of bringing the pathologist into closer touch with the patient. The public health laboratory and the laboratory attached to a voluntary hospital were two different matters; in one case bulk was an important factor, in the other the primary consideration was the individual specimen in relation to the individual patient. In all districts there was an opening for laboratories of both kinds. Most private pathologists were attached to hospitals which could not pay the fees of a whole-time man.

Dr. E. W. G. MASTERMAN (Camberwell) described the peculiar arrangement in his borough where the proposed policy was being carried out at the present time. There was a large Poor-law hospital with a pathological laboratory where all the work of the hospital was done, which was also the municipal laboratory. The pathologist had his own laboratory and assistants where he did private work. The arrangement worked admirably. The voluntary hospitals in the district could not possibly undertake the work done at this institution, and it was not correct to say that this kind of work could only be done at a voluntary hospital.

Mr. H. S. SOUTTAR (Marylebone) said that there was a dilemma here. The general practitioner required pathological reports at the earliest possible moment, and expressed in the clearest possible manner the private pathologist was trying to make a living and the hospital pathologist wanted the maximum possible experience. He suggested amending the resolution by inserting the words "where other pathological facilities are available" after the first clause.—Mr. MCADAM ECCLES seconded this and it was carried after a discussion.—Sir ROBERT BOLAM pointed out that conditions varied greatly in different areas and the prescribed procedure must be kept very elastic.—Dr. HAWTHORNE said that the burden of deciding where other facilities were available would be too great for the Council to bear.

Dr. R. A. LYSTER (Hants) urged that the motion be referred back to Council on the ground that Mr. Souttar's amendment had produced an impossible situation—viz., interference with the responsibilities of local authorities. The motion as amended would hold the Association up to ridicule. Pathologists at present were not a well-established branch of the profession; their future, in his opinion, lay very largely in the development of public health facilities by the local authorities. From these the practitioner also benefited and there was a general tendency now to extend them. Fullest advantage was taken of them and they were much appreciated where they were available. They provided employment for pathologists; the terms of employment were essentially a matter for the B.M.A. The patients benefited by the scale of fees suited to their means. The effect of this motion, if it could be carried out, would be to deprive a large number of patients of pathological help. Thus the three classes of people involved, pathologist, practitioner, and patient, all stood to lose by the resolution. These services, whether for poor or rich, must be developed as one service. The development of a public service for poor people in many directions had produced bad muddles.

Dr. C. E. DOUGLAS (Fife) seconded the proposal to refer back. He said that in Scotland the local authorities always dealt with the examination of specimens sent by practitioners.

Dr. DYKE said that there was a fourth consideration besides those of pathologist, doctor, and patient, and that was the advancement of medicine. This demanded the closest contact between patient and pathologist, which was best served by placing the pathological work concerned with the individual patient in the laboratories of the hospital. He did not agree that the future of the pathologist lay with the public health authorities; it lay in the laboratory of voluntary hospitals. He supported the amendment.

Dr. HAWTHORNE accepted the reference back, which was carried.

He then proposed the fourth recommendation of Council:

That where a pathologist attached to a hospital or medical school undertaking pathological work as a general service does such work for persons able to pay fees, the fees paid for such examinations (subject to such charge for the use of the laboratory as may be arranged) should be the property of the pathologist and should be a matter of private arrangement between the pathologist and the person for whom the examinations are made.

Whereupon an amendment to refer this also back to Council was put forward by Dr. J. HUDSON (Newcastle), who said the proposed arrangement was impossible. This was seconded by Dr. J. STEVENS (Edinburgh) and supported by Dr. F. RADCLIFFE (Oldham), who said that it would put the pathologists in an extremely awkward position. They were whole-time officers of a governing body and they were expected to ask this body to accept a fee for permission to use the laboratory as a private one for part of the time. The day would come when the governing body would observe that their officer was giving much of his time to private work and would consider either his dismissal or the reduction of his salary.

Dr. P. MACDONALD (York) said that the scheme could quite well be carried out, and was being carried out in his own district.

Dr. R. BROCKMAN (Sheffield) quoted another instance where the scheme was working well; the safeguard in this case was that private practice was permitted provided that the staff of the infirmary were satisfied that the work of that institution was being efficiently carried out.

Dr. H. BEADLES (Romford) said that the scheme could not be worked in very large areas, but Dr. HAWTHORNE replied that this type of appointment was not that under consideration in the recommendation.

The amendment was not carried and the original recommendation was passed by the requisite three-fourths majority.

Some discussion arose on an amendment by Brighton to the last clause of the general propositions (vide supra). Dr. PARRY wished to add the words "except at the request of the practitioner" to the phrase stating that reports should only be furnished to a doctor. In places with a moving population like Brighton the requested report might not be ready before the patient left. Mr. BISHOP HARMAN strongly opposed this proposal, pointing out that it was simple for the doctor to forward on the report; the practitioner who had asked for it wanted to see it and he might not want the patient to. The amendment was rejected.

Dr. R. FORBES (Gateshead) thought that all advertisements of commercial pathological institutes should be excluded from the journal and brought forward an amendment to that effect. He mentioned the "transition" type of laboratory, run often by a group of practitioners as a limited liability company. These cut out the private pathologist by charging lower fees, and Gateshead thought it would be better and more consistent with the attitude of the Council towards these institutions if they were not allowed to advertise.

Dr. H. WOODROFFE (Norwich) supported this; he thought that the private pathologist was being left in competition with mass production. If these concerns were to advertise, the private pathologist should be able to also, and that would open the door to advertisements from any branch of the profession.

Dr. HAWTHORNE said that the proposal was ideal, but not practical at present. Many of the institutes had done good service to the profession by providing facilities unobtainable elsewhere. Sir ROBERT BOLAM appealed to Gateshead to leave the matter in the hands of the Council without summary direction, and the amendment was rejected.

Research Work of the Association.

In moving the remainder of the annual report under "Science," Dr. HAWTHORNE referred to the scholarships and grants, especially mentioning a grant to the Paddington Green Hospital special scheme of investigation into child rheumatism. The Stewart Prize, he said, had been awarded to Sir Malcolm Watson in recognition of his work in freeing large tracts of tropical Malaya from malaria, and the Sir Charles Hastings Clinical Prize for a general practitioner to Dr. J. S. Manson, of Warrington, for an essay entitled "Observations on Human Heredity."

In moving the adoption of the supplementary report under "Science," Dr. HAWTHORNE brought forward the motion:

That the Representative Body approve the Council's proposals for the carrying out by the Association of the scheme submitted for collective investigation by individual medical practitioners.

This refers to a proposed collective investigation on varicose ulceration and the after history of gastro-enterostomy. The inquiry is to be conducted, through the divisional machinery of the Association, in the early autumn.

Dr. DOUGLAS pointed out that it was no new thing for the Association to bring together the collective experience of its members; it had been done in the 'sixties. Work on pneumonia and the communicability of phthisis collated in the 'eighties had by now become part of our general knowledge.

Dr. C. E. S. FLEMMING congratulated the Council on the scheme and asked what was to be done with the returns received. He suggested that they should be discussed at branch meetings and at the sections of the annual meeting.

Dr. HAWTHORNE replied that Dr. A. P. Luff, consulting physician to St. Mary's Hospital, had consented to give his services in collating the material. The Ministry of Health had also promised the help of one or more experts in formulating questions and analysing answers.

Municipal Maternity Hospitals.

Proposing the adoption of the report under "Medico-Political," the chairman of that committee, Dr. J. W. BONE (Luton), brought forward the motion:

That inasmuch as the liability of local authorities for the payment of a medical practitioner called in on the advice of a midwife extends over a period of four weeks from the birth of the child, it is not desirable to suggest that the period of responsibility of local authorities should be extended.

This was agreed to, and Dr. FORBES, on behalf of Gateshead, then proposed to amend a resolution passed last year—viz.:

That where a general practitioner is called upon to render assistance at a confinement in a municipal maternity hospital, the fees payable to such practitioner should not be less than the scale of fees approved by the Ministry of Health for the payment by local supervising authorities to medical practitioners called in on the advice of midwives, under Section 14 of the Midwives Act, 1918,

by inserting after the words "a confinement" the words "or for any condition arising directly out of parturition."

Dr. BONE accepted this and proposed the further recommendation of Council:

That the principle of remuneration on a salaried basis for consultative services to municipal maternity hospitals is not unreasonable, but that the actual salary must be governed by the circumstances of each particular case—i.e., the amount of work required and the time occupied—and should bear some relation to the remuneration laid down in the following Minute 95 of the annual representative meeting, 1926. Resolved: That where a consultant is called in by the practitioner in charge of the case the fee should be for the consultation not less than three guineas and for a major operation not less than ten guineas.

This was accepted.

Administration of Anæsthetics by Dentists and N.H.I. Patients.

Dr. BONE reminded the meeting that the Representative Body in 1910, in approving the evidence given on behalf of the Association before the Departmental Committee on Coroners Law, &c., approved inter alia the following:

(1) That it should not be permissible for any person other than a registered medical practitioner or a registered dentist to administer any anæsthetic for medical or surgical purposes.

(2) That registered dentists should be permitted to administer nitrous oxide and local dental anæsthetics, but no other anæsthetics.

(3) That it is undesirable that any person should act both as operator and administrator in the same case where this can be avoided, but it must be recognised that cases occur in practice, especially in sparsely populated districts, in which this responsibility must occasionally be undertaken.

This policy, he said, had now become obsolete, since dentists received special instruction in the use of anæsthetics. A new policy was, therefore, suggested in the following terms:

(1) That no person other than a registered medical practitioner should administer any anæsthetic for medical or surgical purposes, except that a registered dentist may administer anæsthetics for dental purposes only;

(2) That where a general anæsthetic is administered it is undesirable that any person should act both as operator and administrator in the same case where this can be avoided, but it must be recognised that cases occur in practice, especially in sparsely populated districts, in which this responsibility must occasionally be undertaken.

This proposal aroused considerable discussion. Opposition to the new attitude took two main lines: First, that dentists should not be allowed to administer anæsthetics; and, secondly, that it was no business of the Association to express an opinion on what the dentists should do. The first objection was expressed in three amendments, from Willesden, from St. Pancras, and from Birmingham.—Dr. C. F. SCOTT, speaking to the first, said that the General Medical Council had done a wrong thing in allowing instruction to dentists in administration of anæsthetics other than nitrous oxide. Some dentists were becoming professional anæsthetists. There was great danger in this.

Dr. TEMPLE GREY (Marylebone) pointed out that it did not suffice to be specially trained in the administration of anæsthetics; an anæsthetist must know how to treat cases when they go wrong. These were cases of poisoning, and the only man who could be safely trusted to handle a case of poisoning was a duly qualified medical man, who was also the only person in a rightful position before the coroner if death should ensure. Nevertheless, the amendments by Willesden and St. Pancras were lost.

Dr. G. DAIN (Birmingham) then moved:

That the recommendation be amended by the insertion in the second line of para. (1) between the words "dentist" and "may" of the following words: "who has received special instruction in the administration of anæsthetics."

Dr. W. MARRIS (Birmingham) pointed out that dentists themselves had recognised that some of their number were properly qualified to administer anæsthetics while others were not. If their regulations made a distinction there could be no harm in this amendment.—Dr. BONE and Dr. TEMPLE GREY objected strongly on the ground that it was no business of the doctors to adjudicate between the dentists.—Dr. DAIN replied that the Association had held for years that only qualified medical men ought to administer anæsthetics. This policy was now to be modified because there was another body of men trained to give anæsthetics. But the Dentists' Register contained the names of thousands of people who had had no such instruction.

The Birmingham amendment was carried, and on the motion of Dr. D'EWART and Dr. P. MACDONALD the final clause was altered so that the policy as passed read:

(1) That no person other than a registered medical practitioner should administer any anæsthetic for medical or surgical purposes, except that a registered dentist who has received special instruction in the administration of anæsthetics may administer anæsthetics for dental purposes only;

(2) That where a general anæsthetic is administered it is undesirable that any person should act both as operator and administrator in the same case where this can be avoide

but it must be recognised that cases occur in practice, in which this responsibility may justifiably be undertaken.

Dr. BONE then moved :

That the fees for medical practitioners administering anæsthetics for dental operations (as an additional benefit under the National Health Insurance Acts), be as follows : (*a*) For the simple administration of nitrous oxide or a similar anæsthetic, 10*s.* 6*d.* if only one patient is dealt with, but if more than one patient is dealt with at the same time and place the fee should be 7*s.* 6*d.* per patient ; and (*b*) that for other administrations, whatever the anæsthetic, the fee should be one guinea.

An amendment from South Shields proposed to insert the word " minimum " before " fees " in each instance, and others by Worcester and Sheffield desired to make the fee in all cases one guinea and half a guinea respectively, but Dr. Bone pointed out that a bargain was being struck and it was no use passing resolutions asking for unobtainable fees. The scale had been carefully considered in committee. The amendments were all rejected, and after a discussion on emendations of the word " simple " by substituting " short " or " safe " or by omitting it, the motion was carried as proposed.

Dr. BONE then proposed and carried the recommendation of Council :

That it is inadvisable to press for the amendment of the Midwives Act, 1918, in order to secure that local authorities be made responsible for antenatal work to any greater extent than is at present the case.

Dr. M. W. RENTON (Dartford) proposed to refer the matter back to Council for a review of the difficulties of the general practitioner. Local authorities were taking not too little but too much responsibility and much antenatal work was being done by whole-time officers, while midwives were being educated to do the practitioner's work.—Dr. C. FLEMMING concurred, saying that it had come to be expected that district visitors should take pelvic measurements. This was due to the reticence of practitioners in undertaking the work.

Dr. H. M. RAVEN (Kent), Dr. HOWARD STRATFORD (Kensington), and Dr. MIDDLETON MARTIN (Glos.) supported Dr. Renton and urged the importance of keeping antenatal work in the hands of the doctor.

Dr. BONE agreed with the speakers but pointed out that the motion under discussion dealt solely with fees, having arisen out of a resolution of last year's Representative Body on that subject. What was wanted was to find out how the private practitioner could be used to get better antenatal treatment for the people. It was decided to allow Dr. Renton to withdraw his amendment at this stage, and to discuss the matter later.

Orthopædic Treatment.

The Council's report submitted a memorandum on orthopædic hospitals and clinics which came up for discussion under the motion :

That the specialist work of orthopædic treatment, whether at hospitals or clinics, should not be done by whole-time officers, but, on a part-time basis, by surgeons who need not necessarily be devoting all their attention to orthopædic work.

There was a strong feeling among a small section of the members that this would prejudice the quality of the work done. The objection was crystallised in an amendment by Windsor :

That orthopædic treatment, whether at hospitals or clinics, should be undertaken by those who have special knowledge of the subject, and as the needs of the patient to receive the most experienced handling are paramount, no restrictions should be placed on the appointment of full-time officers.

and in another by Miss E. H. JEBENS (Lambeth) and Dr. W. A. SWANN (St. Pancras) to omit the words after " basis." Both were rejected.

Another amendment, which failed, proposed by Dr. E. W. MASTERMAN (Camberwell), seconded by Dr. HOWARD STRATFORD (Kensington), sought to modify the motion by inserting the word " necessarily " or " usually."

Among those supporting the original motion was Dr. E. R. FOTHERGILL (Brighton) who maintained that the interests of the patient and of the doctor were always identical and that there was a serious menace in these clinics to the general practitioner and his work ; the general practitioner, he said, had been, was, and would be the best for the public to look to.—Dr. R. GORDON (Bath) declared that if whole-time officers were appointed to the clinics the general practitioner lost his interest in orthopædic conditions, and it came to pass that these children were never seen by anybody but the specialist, who was apt to treat them without consideration for any other condition from which they might be suffering.—Mr. H. S. SOUTTAR (Marylebone) said that the vast mass of orthopædic surgery in the country was being very well done by general surgeons and deprecated the increasing employment of whole-time workers. The physician, surgeon, or practitioner who was engaged in a general practice could deal far better with any case he took up than could the specialist.

Among those opposing the motion were Dr. G. F. OLDERSHAW (Liverpool) and Dr. DYKE. The latter said that his division considered that orthopædic surgery was a highly specialised technique which did not fall within the province of the general practitioner. There should be coöperation between the surgeon and the patient's own doctor.—To bring about this coördination, said Dr. F. J. HATHAWAY, replying for the Windsor amendment, was the proper duty of the British Medical Association. In so great a profession there must be specialists, and the general practitioner was always able to go up to the clinic and consult about his patients ; in general he was only too pleased to get the best advice he could about them.—Sir RICHARD LUCE said that any advance in surgery had been through a certain amount of specialisation and to pass so general and so sweeping a motion would be a most dangerous thing. It was wrong for the patient and disadvantageous for surgery that the patient should not have the opportunity of consulting a specialist.

Mr. MCADAM ECCLES observed that the thorough treatment of any case could only follow from close coöperation of four people—the orthopædic specialist, the general practitioner, the mother or nurse, and the patient. Orthopædic surgery had got into an anomalous position through a difference of opinion as to what cases belonged to it ; it was not such a wide speciality as many people seemed to think. Specialists were needed at the clinic to see the patient, in the first place at any rate, and general practitioners were needed to take their cases up to the clinic.

Dr. BONE pointed out that the suggestion was to train in each locality men capable of doing the special work.

Eventually the Council's recommendation was carried. The second recommendation,

That existing institutions should be utilised to their fullest extent,

passed without comment. The third was,

That the private practitioner should have free access to the work at hospitals and clinics for the purposes of observation and training, and that his services should be fully utilised by giving him a definite position in the scheme both at the clinic and in the domiciliary care of cases.

In answer to a question, Dr. Bone said that this meant full access to all cases in the hospital, not only his own.

Dr. LEWIS LLOYD (South Carnarvon) pointed out the difficulties that would arise if the patient of one practitioner in a small village were handled and discussed before his colleagues.

The final motion on this subject,

That the arrangements laid down in the B.M.A. scheme for school-children and maternity and child welfare clinics should apply equally in regard to orthopædic clinics,

brought an amendment from East Norfolk :

That the following words by added :—

But that efforts should be made to secure that a more stringent scrutiny be exercised in deciding which cases are, or are not, necessitous, than has been done under

omparable schemes for medical examination and treatment by Education Authorities.

In proposing this, Dr. H. WOODROFFE pointed out that in rural districts many people sent their children to the local school because there was no other. They could quite well afford ordinary fees, but were classed with the others as unable to pay anything. This victimised the general practitioner and the specialist.

The amendment was carried. The arrangements, as thus amended, read :

Briefly stated, the policy of the Association as regards treatment of school-children is to the effect (1) that treatment by an Education Authority should be confined to those children whose parents cannot afford to pay privately for treatment, parents being recommended to secure treatment for their children from their family doctor ; (2) that medical treatment and the treatment of refraction should be carried out by private practitioners; (3) that treatment of the children should normally not be carried out through voluntary hospitals, and that in cases where the work is so carried out, there must have been previous consultation with the hospital medical staff, who should be paid for this work ; (4) that where treatment by private practitioners (whether general practitioners, specialists, or both) is adopted, it should be by means of a "Treatment Centre" or clinic (for Model Scheme, *see British Medical Journal* Supplement, May 8th, 1915, p. 228), or, in sparsely populated districts by "recognition" of places where the local practitioner(s) should carry out the necessary treatment ; (5) that where practitioners in an area are desirous of carrying out treatment of school-children found defective, they should through the Division make representation to the Local Education Authority and place a scheme before that body ; (6) Divisions desirous of placing a scheme of treatment by local practitioners before the Local Education Authority will have the full support of the Association, but for purposes of coördination such schemes should be submitted to the Head Office of the Association prior to being forwarded to the Education Authority ; (7) that it is not part of the policy of the Association to resist the adoption of some other scheme preferred by the Education Authority on the ground that it involves the employment of whole-time officers for the purpose of treating necessitous children ; (8) that a scheme for treatment might be a combination of whole-time and private practitioners ; (9) that there is no objection to treatment by provident dispensaries, public medical services, or other contract medical practice organisations, provided the remuneration of the practitioners is adequate and that effect be given to the principle of free choice of doctor and of patient ; (10) that any scheme for reference of children to the Poor-law for treatment be opposed, but that efforts should be made to secure that a more stringent scrutiny be exercised in deciding which cases are, or are not, necessitous, than has been done under comparable schemes for medical examination and treatment by Education Authorities.

The Representative Body.

It was announced during the course of the day that the Chairman of the Representative Body (Dr. C. O. Hawthorne) and the Treasurer (Mr. Bishop Harman) had been elected unopposed. A contest for Deputy Chairman resulted in the election of Dr. A. Lyndon. The following gentlemen were elected to the Council, without opposition in all cases but two, by the votes of the "group representatives" : G. B. Hillman, I. W. Johnson, A. M. Webber, J. R. Prytherch, E. B. Turner, W. Paterson, H. C. Bristowe, A. Lyndon, G. W. Miller, J. Patrick, R. C. Peacocke, and J. Armstrong.

A MEMORIAL TO LORD LISTER.—Bishop Hamilton Baynes has dedicated two beds in Birmingham General Hospital, one to commemorate the beneficial work of Lister, and one endowed by university students from funds collected at last year's carnival. A stained glass window in the hospital chapel was dedicated at the same time in memory of the late Sir John Holder.

HAMPSHIRE HOME OF RECOVERY.—Hitherto this home at Stoneham Park has only been able to receive men recovering from surgical operations. An effort is now being made to provide a new wing for the benefit of women patients. The home receives patients from the four general hospitals in the county as soon as they can be moved.

CONGRESS OF THE ROYAL SANITARY INSTITUTE.

HASTINGS, JULY 11TH TO 16TH.

WE have already reported the opening proceedings of the Royal Sanitary Congress which met at Hastings last week under the presidency of Sir WILLIAM JOYNSON-HICKS, Secretary of State for Home Affairs. The work of the sections continued until Friday, and on the following day there were excursions in the neighbourhood.

Personal Hygiene.

Sir JOHN ROBERTSON (Birmingham), in his presidential address to the Section of Sanitary Science and Preventive Medicine, said that people were expected to pick up the knowledge necessary to keep themselves in good health. He was well aware that the medical profession was far from knowing all that should be known about the care of the body. Nevertheless there was a great difference between the knowledge possessed by the physiologist and the knowledge requisite to keep the body in health. He thought the latter should be a really important subject in the educational curriculum. Two things were lacking at present : first, an appreciation by the public of the value of such knowledge ; and, secondly, a group of well-informed teachers. People who really understood the needs of the body would refuse to work under unwholesome conditions and employers would recognise that these conditions were damaging. The subject of elementary physiology ought to be made a real living thing. The Medical Research Council was a very fine organisation for investigating problems of the causation and prevention of disease, but its investigations did not bear the fruit they should. What was needed was general recognition of the fact that much ill-health was due to lack of knowledge, and he hoped that the new London School of Hygiene would do a great deal in preparing teachers to go out into the districts and spread this necessary knowledge.

Roads and Towns : Uses of Sewer Gas.

Mr. LESSEL MCKENZIE (Bristol), President of the Conference of Engineers and Surveyors, said that road engineers had every reason to be satisfied with the progress made since the war in producing impervious surfaces with little dust and no need for watering. In Bristol 5000 houses had been built, which almost met the demand of those able to pay the rent, and they now had to face the problem of providing houses for those unable to pay more than 6*s.* or 7*s.* a week, many of whom were living under appalling conditions. The tendency in town-planning nowadays was to lay down the skeleton of a scheme and make the details as elastic as possible. Planning of areas already built on was exceedingly difficult. Useful work in regional planning was being done in some parts of the country, but there was no statutory power behind such schemes. Instead of each authority having its own undertakings, it would often be much more economical to have joint schemes. As regards refuse disposal destruction by burning was costly and a preliminary screening of the refuse was to be commended. The working of the new plant, designed by Messrs. Woodall and Duckham, now being tested in London, would be watched with interest.

Mr. McKenzie went on to refer to the production of gas from sewage. At the Gross Zieter sewage works in Germany a gas was produced which gave the necessary power for the works and was supplied to a population of 8000 for domestic purposes. At Emfort a net profit of £4200 was said to have been obtained last year by the utilisation of sewer gas. In conclusion, Mr. McKenzie expressed the opinion that cremation would have to be accepted as the only proper way of disposing of human remains.

Changes in the Poor-law.

Mrs. DYMOND (Mayoress of Hastings), in her presidential address to the Conference of Health

Visitors, referred hopefully to the proposed abolition of the guardians and the handing of their functions to county councils and county borough councils. At present there was much waste of time and irritation caused by several bodies collecting the same information. For example, the health visitor obtained all the information about a family; the man lost his job and the same information was obtained again by the labour exchange; the man applied to the guardians and the information was obtained a third time by the relieving officer. If the proposed change were carried out the local authorities would not have to submit insignificant items for the approval of the Ministry, the stigma of pauperism would disappear, and the change would benefit many children. The children at present boarded out by the guardians would come under the care of the health visitors and also the children boarded out under the Childrens Act of 1908. In many unions the inspection of such children was still carried out by a man. Most men, except doctors, were helplessly at sea with a baby and depended for their information on the foster-mother, whom they were supposed to inspect. The present method of supplying orders for admission to the Poor-law maternity wards was also open to criticism. The details had to be given by the applicant to a male relieving officer, whereas under the new scheme the necessary inquiries would be made by the health visitors.

Welfare Work and Hygiene in Factories.

Major ISIDORE SALMON (London), in his address to the section of Hygiene in Industry, considered this question under two headings: (*a*) personal hygiene as it applies to the work, and (*b*) factory hygiene as it applies to the production of food in the factory. As regards the first he was convinced that the care of the human machine should be an integral part of the organisation of any business. In the rough division of departments into productive and non-productive, welfare work was unfortunately classed among the latter, but should be classed among the former. Encouragement during convalescence was one important item. Many modern works welfare departments had their clinics, medical officers, dental surgeries, manicure and pedicure sections, massage and electrical treatment rooms. Others, too, had consultant hospital and convalescent services. His opinion was that every welfare section should carry out extensive home sick-visiting for the gradual absorption into active work of all who had been on the sick list. Industry as a whole, and consequently the nation, benefited enormously from sane welfare work. The slogan "Safety first" should apply to disease. One important factor was the right "placing of the staff."

Hygienic production of food was of increasing importance owing to the modern tendency to buy prepared foods and to take meals away from home, and the betterment of the conditions under which food is produced was looked after in his firm by a comprehensive laboratory service quite separate from the department which supervised the personal hygiene of the staff. As one example the phenomenal growth of the ice-cream industry made supervision of all the processes of production and storage extremely necessary. When the ice-cream was once frozen little change took place in the bacterial flora. In the various States of the U.S.A. there were various bacterial standards for ice-cream, but here there were none. Again, in the case of prepared meat products, preservatives were only allowed in the manufacture of sausages, and consequently the quality of the raw products should be controlled. It was a stupendous task for large firms to live up to the standard of bacteriological cleanliness required by modern conditions. Factory disinfection often covered up bad conditions, and the indiscriminate use of disinfectants should be condemned both in the interests of the workers and the quality of the foodstuffs. Factory ventilation had received insufficient attention. In a recent visit to China he had found the hygienic conditions of the food-packing factories equal to anything in England or the U.S.A.

The new Factory Bill now under consideration was meeting with opposition from progressive industrialists because they were afraid of the extended powers which gave to Ministerial rules the force of law. Hygiene in industry would be impeded rather than stimulated by an Act which placed such power in the hands of bureaucrats. Lastly he thought the application of hygiene to industry would do much to improve the relations between employer and employed.

Rheumatism.

Sir WILLIAM WILLCOX (London), in a lecture to the Congress on July 12th, discussed the causation of various forms of rheumatism, and showed how much disablement was due to chronic arthritis. More statistical research was needed, he said, to determine the influence of occupation. He referred to the influence by focal sepsis, constitutional predisposition, the condition of the skin, and external influences such as climate, damp, diet, and occupation. He expressed his belief in the provision of dental clinics for industrial workers and in the extension of the provision of baths to other industries besides collieries, and in the establishment of clinics for rheumatic diseases which would act as clearing-houses and thus enable the facilities of spa treatment to be retained for those likely to benefit therefrom.

Dr. A. ROLLIER (Leysin, Switzerland), in an address to the Conference on Health Resorts, referred especially to the use of heliotherapy in combination with sea-bathing in the treatment of rheumatism, and went on to emphasise the need for providing suitable work for patients suffering from these chronic diseases in order to combat the deadly combination of boredom and despair induced by the monotonous routine of treatment.

Dr. FORTESCUE FOX spoke of the value of British spas, whilst Dr. M. B. RAY, Mr. W. A. APPLETON (General Federation of Trade Unions), and Mr. JOHN HATTON (British Spas Federation) dealt with the provision of spa treatment for insured persons. Mr. Hatton described a scheme by which 30,000 cases a year might have a four weeks' course of treatment with existing bathing accommodation. The scheme involved no fresh administrative machinery and no capital outlay, he said, and could be started without delay.

Small-pox.

There was keen discussion at the Section of Sanitary Science on the measures needed to control small-pox. Some speakers believed that the mild type of variola is so different from ordinary small-pox as to deserve a distinguishing name—e.g., variola minor or para-smallpox. They thought that the mild type can be trusted to breed true, that it is not more serious than chicken-pox, and that an outbreak of this disease does not justify legislation to tighten up infant vaccination or wholesale revaccination. Dr. C. K. MILLARD (M.O.H., Leicester) thought that when an outbreak occurred the name small-pox should be used only until it was known which variety was present.—Dr. R. P. GARROW (M.O.H., Chesterfield), after six years' experience, found variola minor was still breeding true. Other speakers, however, adopted the view that the type may change at any time and that the ordinary small-pox precautions should be taken for variola minor. It was generally accepted that both types of the disease immunise the patient against vaccination, but after variola minor the immunity only lasts a short time. Up to now there has been practically no mortality from the mild type of the disease. Vaccination protects against both types.—Dr. C. S. THOMSON (M.O.H., Deptford) suggested that one of the reasons why people object to vaccination is that it is compulsory. Only 30 per cent. of the infants in Deptford were vaccinated, he said, but he had been able to get 90 per cent. of the school-children immunised against diphtheria. Other speakers thought that reliance solely on vaccination had retarded research as to methods of treatment, especially with serums.

Another suggestion was that the objections to vaccination might be minimised by perfection of technique and by using a milder form of vaccine which would give immunity for the period of an epidemic.

Notifiable Diseases of the Nervous System.

Papers on this subject were read by Dr. F. M. R. WALSHE, Dr. SALUSBURY MACNALTY, and Dr. J. A. H. BRINCKER (London), attention being chiefly devoted to poliomyelitis, polio-encephalitis, and encephalitis lethargica. A discussion followed, towards the end of which Dr. DUNCAN FORBES (M.O.H., Brighton) pointed out that not much hope had been held out from the preventive point of view.—Colonel A. H. TUBBY (London) gave a warning against the use of electricity and massage before the destructive stage of acute poliomyelitis was quite over, and emphasised the need for continuity of treatment. Each case should be in charge of one physician and one surgeon from the beginning. It was mentioned that the experts of the London County Council were available for aid in diagnosis in districts near London.—Prof. JAMES MCINTOSH (London) showed that very many of the clinical diagnoses of encephalitis lethargica were not confirmed at the post-mortem.

Bovine Tuberculosis.

The Section of Veterinary Hygiene dealt with the effect of recent legislation on tuberculous infection in milk. Many county boroughs until recently have held the powers conveyed by the "milk clauses," which enabled their veterinary inspectors to go into other districts to search for cows with tuberculous udders in the herds supplying them with milk. Mr. J. S. LLOYD (veterinary inspector, Sheffield) expressed disappointment at the loss of these powers, and a good deal of sympathy was expressed with his view, but the consensus of opinion at the meeting was that the new powers given by the Tuberculosis Order and the Milk Act were so recent that the county councils had not yet had time to develop their machinery. It was agreed that many counties were quite inactive; others, however, were taking energetic measures.—Dr. W. M. ASH (M.O.H., Derbyshire) advocated dealing with tuberculous cows entirely under the Tuberculosis Order and leaving the more cumbersome procedure of the Milk Act alone. He showed that in this way very many tuberculous cows had been condemned, and good coöperation without red tape had been established between the veterinary departments of the county council of Derbyshire and the county borough of Sheffield.—Dr. LEIGHTON (Edinburgh) spoke about the large number of tuberculous cows which had been condemned in the neighbourhood of Edinburgh, and several speakers asserted that the new powers were being well used in Scotland. Some favoured whole-time, others part-time veterinary appointments.—Colonel BRITTLEBANK (veterinary inspector, Manchester) agreed that there had been a temporary setback owing to the transfer of the powers and that the percentages of tuberculous mixed milks had shown an increase, but he thought they should exercise patience and give the new legislation a chance. The difficulty of keeping tested herds tubercle-free was discussed. Colonel Brittlebank mentioned that tubercle bacilli were sometimes found in Certified Milk. The explanation of the reinfection of tested herds which were maintained by breeding only was to be sought, it was pointed out, in infected pastures, the introduction on to the farm of infected manure, and other accidental contaminations. An instance was cited of the infection of a tubercle-free herd near Edinburgh owing to a stray cow finding its way into the herd. The stray cow was afterwards found to be tuberculous, but had spent half a day in the tubercle-free herd. At the next half-yearly testing four cows in the tested herd gave a reaction. A speaker from Shanghai said the cattle from the hills showed no tubercle, while those from the dairy farms were heavily infected. An Australian speaker did not agree, but said he had found in some instances 30 per cent. of tuberculous animals among steers in Queensland living in the open.—Mr. E. G. BURNDRED (veterinary inspector, Blackburn) thought the veterinary inspection for Grade A milk should be quarterly.

The following resolution was adopted on the proposal of Prof. G. H. WOOLDRIDGE (London):

"That the time has arrived for the control of the sale, distribution, and use of tuberculin and the standardisation of the methods of its preparation."

Puerperal Fever.

The Maternity and Child Welfare Section devoted one morning to the discussion of puerperal fever. Dr. J. BRIGHT BANISTER (London) described the coöperation necessary to bring about a better obstetric system and the prevention of puerperal fever. First of all the public, and especially the women, must demand a higher standard of antenatal supervision and a greater regard for bodily hygiene. Secondly, the local authorities must provide better housing conditions and efficient sanitary service—he had had, for example, special reason to complain of the removal of refuse in London—and should supply sterilised outfits for confinements in their area. Thirdly, there was the part of the doctor or midwife on whose behalf he pleaded for sympathy, as she often had to do her work under very difficult conditions. He emphasised the importance of removing septic foci and of the care needed to avoid conveying infection.

Dr. A. REMINGTON HOBBS described a method of promoting drainage of the uterus by the introduction of glycerine without an anæsthetic and without injury to the cervix or discomfort to the patient.

MIDDLESEX HOSPITAL.

NEW INSTITUTE OF BIOCHEMISTRY.

Prince Arthur of Connaught, chairman of the board of governors of Middlesex Hospital, accompanied by Princess Arthur, presided on Wednesday last at the laying of the foundation-stone of the new Institute of Biochemistry, for the provision of which Mr. S. A. Courtauld had made a magnificent gift of £30,000.

Prince ARTHUR said, in the course of a brief speech, that he would take the opportunity of making a very welcome announcement. "Mr. Courtauld," he said, "is so determined to ensure that the workers in this department of scientific endeavour shall lack nothing in these researches that he has now increased the amount of his list from the noble sum of £30,000 to the princely sum of £40,000. I will not dilate upon our further indebtedness to his great liberality. I will only assure you that we all thank him most warmly from the bottom of our hearts."

The proceedings opened with a brief address from Sir JOHN BLAND-SUTTON. He said:—

Biochemistry in Relation to Medicine.

Dictionaries printed before the year 1900 contain no such word as biochemistry. The name is now familiar, and, though new, the science is old; it was founded by Lavoisier at the end of the eighteenth century. Biochemistry is concerned with the application of the principles of chemistry and physiology to the study and interpretation of the phenomena of life. Some 250 years ago Linnæus, the great Swedish naturalist, arranged the kingdoms of nature in three classes: minerals, plants, and animals. He defined his famous trilogy in this terse way: Stones grow. Plants grow and live. Animals grow, live, and feel. The three kingdoms were for many years believed by naturalists to be distinct from each other.

The history of great discoveries shows, in many instances, that they were unappreciated for a century or more. This is true of biochemistry. The microscope revealed to able investigators like Ferdinand Cohn, Pasteur, Koch, and their followers, the existence of myriads of minute living things concerning which biologists were puzzled to decide whether they were plants or animals! Such discoveries bridged the gap between plants and animals, and the close study of these minute organisms—microbes as they were called—proved them to be the causes of fermentation, putrefaction, and suppuration; and many infective diseases.

Primitive man, who personified the sun and moon, the wind and sea, regarded disease as due to the action of demons. The discovery of microbes gave colour to the ancient belief that disease is due to something which enters the body of man. We know to-day that the microbes of disease and parasites enter our bodies with the air we breathe; with food, and with water. Many are stealthily and unsuspectedly conveyed to us by biting insects, such as fleas, flies, gnats, and ticks, and even by snails. The study of bacteria and micrococci has taught us that some forms of infectious disease, such as tetanus and gas-gangrene, are derived from cultivated soil saturated with animal manure, and some are parasites of plants which have transferred themselves to man and have acquired for animals, as well as for man, virulent properties. There are many diseases obviously due to microbes, but the actual agents have not yet been detected. Now that the gulf is bridged between plants and animals, it is the ambition of biochemists to discover the connecting link between stones and plants in order to find out how life arose from inorganic matter.

The laboratory, of which the foundation-stone is to be "well and truly laid" is not primarily intended to solve such matters. Men capable of judging the effects of biochemistry on the practice of medicine believe that it will ultimately promote human welfare by helping man to protect himself from such things as the deleterious effects of environment, the struggle for food, and the germs of disease which surround him on every side. It is also intimately concerned with the processes of life which begin with man's conception and continue throughout the subsequent phases of his life. It will help him to fulfil Kipling's fine

"Be fit—be fit, in mind and body be fit."

Just as the flame of a candle is produced by the oxidation of organic matter, so is the heat of the body maintained by smokeless combustion of foodstuffs and muscular action—work. This is the flame of life, and the expression is something more than metaphor. Few sentences contain so much in few words as the phrase, "conservation of energy"; it applies to the mechanism of life, as well as to machinery.

I have always maintained that laboratories for investigating disease should be in close association with hospitals concerned with the cure of disease. The future of medicine does not lie in prescribing drugs. The day may come when the biochemical laboratory will displace the dispensary. Lavoisier was the founder of biochemistry. In 1794 his head was cut off by the apostles of liberty, equality, and fraternity, on the excuse that the Republic had no need of scientists! Mr. Courtauld has no fear that such a fate awaits him. Judgment is a necessary adjunct to benevolence, and the wisdom shown in building this laboratory indicates his keen appreciation of the great part science plays in practical medicine. Mr. Courtauld, by helping our medical school in this way during his lifetime, can be satisfied that the money he gives will be devoted to the object he has at heart. The laboratory will be useful in the daily work of the hospital. It is said of Linnaeus that he imbued his pupils with his own intense enthusiasm and acquisitiveness; if our excellent professor of biochemistry emulates Linnæus we may be hopeful that a discovery will one day be made within the walls of this laboratory which will make the world gape with astonishment.

Mr. Courtauld's Beneficence.

Mr. Courtauld then laid the foundation-stone, when Mr. S. G. ASHER, chairman of the Medical School Committee, moved a vote of thanks for his great generosity, which was seconded by Mr. A. E. WEBB-JOHNSON in the following words:—

In speaking, I cannot but cast my mind back to before the war, when Sir John Bland-Sutton showed his faith in the scientific future of this medical school by his gift of the pathological institute which bears his name.

We are present at a ceremony which marks a tremendous advance in the placing of scientific medicine in this country on a firm basis. Biochemical laboratories there are already in some of our universities, but a great biochemical institute attached to a large general hospital and medical school is the right way to help the advance of medical education and research. The foundations of scientific work in this school were laid deep in the past. They were made secure by Sir John Bland-Sutton. This development which is initiated to-day reinforces those foundations and makes the superstructure also secure for all time.

We owe the present great advance to our friend, Mr. Courtauld. It is not the first indication of his interest in medical research and education, for it is but a few years since he gave £20,000 to endow the chair of anatomy, one of the fundamental medical sciences.

Among the happiest results of my work for this medical school have been the friendships which I have made, and one which I cherish most closely is that which I am privileged to enjoy with Mr. Courtauld. Since I have known him well I have learnt to appreciate his earnest desire to do all in his power to improve the lot of those who are less fortunately placed than he. Near his home and amongst his own people his efforts are directed to improving the housing, providing clubs and recreation rooms for the young, hospitals for the sick, and homes for the aged. That is the immediate task before his eye, but he has had a greater vision. He has been inspired to come to headquarters and has realised that by giving his support to medical education and research he reaches the very factory of medicine where new discoveries are made and men are taught to apply those discoveries for the benefit of all mankind.

Mr. Courtauld has done more than give. His presence here to-day is a further indication of his personal interest, and I have the greatest pleasure in voicing our thanks to him for himself laying this stone. The inherent vital elements in this great institute will be the men who work in its walls and the ideals which they cherish and teach. The donor need have no qualms for the future, for his gift could not be in safer hands than those of Prof. Dodds, who will have the cordial coöperation and support of Prof. McIntosh.

A vote of thanks to Prince Arthur of Connaught for presiding was proposed by Lord MILDMAY OF FLETE, and seconded by Mr. ERIC PEARCE GOULD, and cordially received.

The New Building.

The new Institute will adjoin the hospital and be entered from Union-street. In its structure as well as equipment Mr. Alner W. Hall, the architect, has met the requirements of expert advice, and especially the desires of Prof. E. C. Dodds, who will be the director. Much recent successful work falling under the general and inclusive heading of biochemistry has made it possible to foresee with some certainty the various laboratories which will be required, and how they should be equipped to deal with the different ramifications of a growing science. Having regard to the increasing literature, directly or indirectly connected with biochemistry, the architect has made arrangement in his plans for a reference library.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

ANNUAL REPORT OF THE COUNCIL.

THE Council reports a year of satisfactory work, with substantial increase in the membership and in the financial resources of the Society. 1057 new members have been elected during the year, the loss of members through death and other causes being 308. On Dec. 31st, 1926, the number of members was 10,070.

The number of applications for advice and assistance from members was 961, as compared with 801 for the year 1925 and 785 for 1924. In a large majority of the cases satisfactory results were obtained without litigation, and the results of most of the cases in which litigation occurred were satisfactory. The Council acknowledges with appreciation the skill and energy with which the Society's solicitors—Messrs. Le Brasseur and Oakley—and the secretaries, conduct the work of the Society.

It is noted that within the past year several practitioners have joined the Society after having already become involved in serious litigation which, of course, could not be undertaken for them on that account, although certain assistance has been given. With a view to encouraging young practitioners to join the Society as soon as they become registered, no entrance fee is required from them if they apply for membership within a year of the date on which their names are entered on the Medical or Dentists' Register.

Solicitors' Report.

This year is marked chiefly by the first defence in respect of a capital criminal charge which the Society has since its commencement been called upon to undertake. The gravity of the case, when first before the Society, was immediately appreciated, and prompt steps were taken for the protection of one of the two doctors concerned. The other, at that stage, not realising the gravity of his position, had not then applied to the Society. On the face of the depositions the case appeared to present insur-

mountable difficulties in the defence, but after its very careful investigation and consideration, the Society was satisfied as to the innocence of both its members and eventually secured their acquittal. In its initial stages the Society was hampered by the failure of one member concerned to apply for its assistance, but fortunately the member realised in time the extreme gravity of his position, and from that moment the Society had the matter entirely in its own hands.

Another matter again emphasised is the neglect of certain practitioners in the use of X rays. It is not suggested that this necessarily implies neglect, but that an X ray is a protective measure; without it a member's position is prejudiced should a claim be made against him. Some cases are cited where the Society has been put to considerable expense, as also the member, through this matter. The solicitors say: "Some members do not seem to heed the Society's warning, and only learn by experience, and it might well be considered that the Society should penalise their members who without adequate reason neglect to obtain X rays wherever possible, or, should this advantage be refused by the patient, to have such refusal recorded in writing."

Examples of Alleged Negligence in Fracture Cases.

A member treated a child for a fracture and both before and after setting the fracture employed X rays. The arm was strapped up in position, and directions given to the mother that it was not to be moved nor the strappings interfered with. After doing this the member did not visit the child for a period of some eight days. As his attendance had not been sought for nor any matter brought to his knowledge, he had felt justified in allowing the length of time to elapse. On the next visit to the child he found the fracture to be in an unsatisfactory state with evidence of the strappings having been interfered with. The patient was then removed out of his care and allegations of negligence were made against him. Unfortunately the doctor on his own initiative, and without obtaining any advice from the Society, made a verbal offer to the patient's parents to bear the expense of such other treatment which had been obtained, and when subsequently allegations were made against him and expert opinion obtained, it was considered that the member was placed in a very difficult position by reason of his gratuitous offer. In all the circumstances it was deemed advisable in his interests to arrive at a settlement.

A claim was made against a member in respect of a fracture of the forearm which had united badly, necessitating a subsequent operation. The fracture had been treated under the guidance of X ray photographs, and during his absence his partner had sent the patient into hospital, not being satisfied with the union of the fracture. Later on the patient was seen by a consultant who reported that there was a malunited fracture. After operation it was reported that the ununited ends of the fractured bone were put into perfect position and fixed with metal plates, the arm then being fixed in a plaster case to be kept on for eight weeks. The patient was informed that he had no just cause for complaint against his medical attendant, and all liability was repudiated on his behalf. Nothing further was heard of the case.

A complaint was made against a member in reference to his treatment of a fractured wrist. The fracture had been X rayed and put up on a Carr's splint and did well until the splint was removed and massage was employed. The doctor had given instructions that the splint was to be applied at night, but this was not done, and the patient used her hand although warned not to do so. Deformity ensued, and the patient was taken to a specialist who operated on the wrist. The patient's husband said that the cost to him had been £150, and he expressed surprise that an account should be sent in for medical attendance. A reply to the husband's letter was drafted for the member to send, and as he did not wish to sue for his fees and no action was taken by the patient or her husband, the matter was allowed to rest.

Various other typical cases dealt with are summarised under the headings Negligence and Unskilfulness, Libel and Slander, Medical Ethics.

Professional Secrecy.

Some of those quoted under the last heading are of especial interest in view of the recent debate on this subject.[1]

[1] THE LANCET, 1927, ii., 14.

The Society's comments, which precede the summary of illustrative cases, are as follows:—

It is the duty of a medical adviser to keep secret all matters concerning his patients which become known to him in his capacity of doctor. Nothing should induce him to disclose what, in his professional capacity, has come to his knowledge, unless he first has the consent of his patient to the information being given; and the patient's consent ought, if possible, to be in writing and signed by the patient.

The rule of absolute secrecy as regards what comes to a medical man's knowledge professionally should be observed almost without exception. Where, however, a medical man by keeping silent becomes passively acquiescent in the intended perpetration of a crime, the carrying out of which he can effectively stop if he reveals what he knows, then he should make it clear to his patient in the first instance that, if the crime is persisted in, it will be his duty to break the rule of secrecy.

The Council of the Society considers that it is the duty of a medical man *not* to disclose the nature or circumstances of the disease or illness from which his patient is suffering unless he is satisfied that the inquiry is made by a near relative who has a bona fide obligation to maintain the patient or to assist in securing the comfort or the recovery of the patient. Such disclosure is not to be made in any case where the patient is able to consent and has not actually consented. This rule does not apply when there is a statutory obligation to disclose (this includes insanity and notifiable diseases), or where the disclosure is ordered by a competent court of law.

A member received a request from a lady for information as to statements made to him by relatives of a man who had been under his observation in regard to his mental condition. He had already declined to give any information, and he was advised to adhere to that position.

A member received a request from a postmaster that he should state the ailment from which a post-office employee was suffering to whom he had given a sickness certificate of unfitness for work. He was advised to tell the postmaster that he could give the information asked for only with the consent of the patient, and that if her consent was obtained he would supply the information.

In a case where exception was taken by a judge at the Old Bailey to a doctor giving information about a patient of his to the defendant's counsel, the Society advised the doctor to see the judge privately, and after his interview with the judge there was no occasion for the Society's intervention.

A member asked if he should inform the mother of a girl who had told him that she feared she was pregnant as she had missed her periods for two months, and who had asked him if he would help her to prevent pregnancy. She remarked that she would commit suicide otherwise. The member was advised not to inform the mother, unless he had reason to believe that there was any likelihood of the girl attempting suicide, which in this case did not appear to be so.

A member received a request from the solicitors of a patient to be supplied with a report of his attendance on her. She had suffered from gonorrhœa and was contemplating divorce proceedings against her husband, who had also been attended by the doctor for gonorrhœa. The member was advised that he could properly supply the solicitors with a full report of his attendance on their client, but should not give them any information in regard to the husband unless subpœnaed and required to give evidence about him.

A member asked whether he ought to report to an insurance company a fact connected with a patient's previous ill-health of which he had not been informed when filling in a form for the insurance company. He was advised that he should not report the matter to the insurance company, but should warn his patient of the possibility of the withholding of any material fact affecting the validity of the insurance, leaving it to the patient to inform the company or not, as he thought right.

Protection in Many Aspects.

Examples of difficulties in connexion with partners, assistants, and locum tenents that have been smoothed out after consultation with the Society are set out. Attention is drawn to problems of notification, and a list of cases in which medical practitioners are required to send a notification to a public

authority is appended. Some of the advice given to members who have asked for guidance as to the ethical position in connexion with articles or advertisements in the public press makes interesting reading.

Sections on buying and selling practices, coroner's inquests, medical certificates, medical evidence, Poor-law medical officers and public vaccinators, unqualified medical practice, income-tax, and dental practice conclude a document which is very much more than a mere annual report of the activities of the Society. The financial position remains strong, the surplus funds amounting to £40,600 at the end of 1926, against £38,300 the previous year.

Members are urged, in their own interest and in that of the Society, to refer matters immediately to the Society *before dealing with them in any other way*. Every year loss accrues to the Society, and to the members concerned, by neglect of this precaution.

NATIONAL HEALTH SERVICES IN IRELAND.

(FROM OUR OWN CORRESPONDENT.)

IN May, 1924, the Minister for Finance appointed a committee of inquiry with the following terms of reference :—

(1) To report on the advisability of the continued maintenance of the system of National Health Insurance in its present form and to make any recommendations considered proper in that connexion.

(2) To consider whether it was desirable to institute a system of medical treatment on a contributory basis, and, if so, to advise the form such system should take.

(3) To report on the question whether the medical services at present assisted or maintained out of State or local funds could be improved as respects efficiency and economy; and, if so, in what manner, due regard being had to any recommendations under the preceding paragraph (2).

An interim report was presented to the Minister in February, 1925, and the final report has now been published. A majority of the committee makes a series of recommendations, which they summarise as follows :—

National Health Insurance.

(*a*) The termination as from Dec. 31st, 1927, of the National Health Insurance (Prolongation of Insurance) Act, 1921.

(*b*) The extension of medical benefit to insured persons, with an increase of 2*d*. in the existing weekly contribution rates, to be borne equally by the employer and the employee.

(*c*) The diversion to medical benefit of the monies set free from insurance funds consequent on the abolition of insurance committees and the transfer to local authorities of responsibility for the treatment of insured persons suffering from tuberculosis.

(*d*) The payment by the State of compensation to local authorities in view of the additional burden placed on their funds by the transfer to them of responsibility for the treatment of insured persons suffering from tuberculosis.

(*e*) The provision of four whole-time district medical referees on a permanent basis in connexion with the National Health Insurance scheme.

Poor-law Medical Services.

(*a*) The extension of the Dispensary Nursing Service, especially in those areas on the western seaboard which are not already covered.

(*b*) The provision by the State of substantial aid towards the cost of erecting, remodelling, and reconstructing central dispensaries as and where required.

(*c*) The remission or refundment (in whole or in part, according to the circumstances) of taxes incident to motor usage in the case of doctors, nurses, and midwives engaged in the public service in rural areas.

(*d*) The extension of the Education (Provision of Meals) (Ireland) Acts, 1914–17, to rural districts.

(*e*) The provision of financial assistance for the construction, modernisation, and equipment of county and district hospitals and institutions.

(*f*) The establishment of a national (dispensary and hospital) medical service.

(*g*) The recoupment by the State of one-half of the salaries of the county medical officers of health.

(*h*) The setting up of a standing council to advise and assist the Minister of Local Government on health matters.

(*i*) The appointment of a small committee of scientific experts to devise a scheme of medical research suitable for the Irish Free State.

Two members of the committee submit a minority report, which is mainly devoted to criticism of the proposals of the majority, and particularly of those for the provision of medical benefit for insured persons, and for the establishment of a national medical service for the treatment of poor persons. One definite proposal is made with regard to the treatment of the sick poor in the four county boroughs in the Free State—namely, that arrangements should be made with voluntary hospitals for the provision of dispensary treatment for poor persons, and with medical practitioners for domiciliary treatment.

The outstanding features of the majority report are the recommendations for the provision of medical benefit for the insured, and for the establishment of a national medical service for the treatment of the poor. Both these recommendations have been made by several previous committees which have inquired into the public medical services of Ireland, and in principle, at any rate, they have been accepted by the medical profession. There is certain to be public opposition to both of them on the ground of expense. The committee admit that its present proposals are not the best that they could put forward, but they are deterred by considerations of expense from recommending the adoption of a thorough and comprehensive medical scheme, of the outlines of which they give particulars. Dr. Robert J. Rowlette, who signs the majority report, dissents from his colleagues on this point, and recommends the establishment of a comprehensive scheme of medical services forthwith.

It is not likely that any step will be taken by the Government on the report until they have had the opportunity to study the cognate report of the commission on the Relief of the Destitute Sick and Poor, which is said to have been completed, and to be now in the process of printing.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

A Sign of Hepatic Insufficiency.

NOT enough attention has been drawn, says Dr. Noël Fiessinger, of Paris, to a sign of gross hepatic insufficiency which may be observed in the mouth. On inspecting the buccal and pharyngeal mucous membrane, he states, it is common to see a special red colour—a vivid carmine—over the palate, the throat, and the inner side of the cheeks; the tongue also may show this discoloration at the tip, at the sides, and often also at the base. In serious cases it peels completely and is as glazed as in typhoid, though more red. The patients complain especially of heat or dryness in the mouth. The sign is seen especially in alcoholic cirrhosis, in severe icterus, and in serious toxic and infective states; or sometimes in the course of a mild chronic jaundice. When seen, it suggests that the condition is serious, requiring rigorous treatment and absolute rest, and the prognosis should be very guarded. When the colour persists it must give rise to a fear of complications such as gastric hæmorrhage or severe jaundice. It is apparently due to vascular degeneration; on each side of the uvula one may see varicosity of the capillaries.

Heliotherapy in France.

Until quite recently there were no institutions for heliotherapy in this country of the type familiar in Switzerland. This deficiency is, however, now being made good. A sanatorium for the treatment of non-pulmonary tuberculosis has been opened at Courmettes, in the Alpes Maritimes; a second, particularly well equipped, at Odeillo, in the Pyrénées Orientales. The third, at Briançon, is exclusively for ex-Service men.

An Index Analyticus Cancerologiæ is to be published by the French League against cancer, and will contain the names of works on this disease, written in all parts of the world. National committees will supply bibliographical data from the more important countries. The general secretary is A. Lacassagne, 26, rue d'Ulm, Paris, 5e, and the index will appear every three months. For countries outside France, the annual subscription will be 60 francs, and copies are to be obtained from Masson and Cie, 120, Boulevard St. Germain, Paris.

The Association for the Development of Medical Relations, whose office is at the Faculté de Médecine, 12, rue de l'École de Médecine, Paris, is becoming more and more effective as an aid to foreign students in France. It serves as a general information bureau, and medical men desiring to follow post-graduate courses or to attend hospital work in Paris will find it very helpful.

A model hospital for the treatment of infectious diseases has just been completed at Orleans. Patients are isolated in glass-walled compartments, special baths are given when patients enter and leave, and all furniture and utensils may be cleansed with chlorine antiseptics.

Scholarships providing free tuition for the first year of medical study have just been provided by the French Government for students whose grades in the preliminary baccalauréat and science courses are sufficiently high. These scholarships are awarded to those who gain a sufficient number of marks and are not on a competitive basis.

A course on the plastic surgery of the face and neck will be held from Sept. 16th to 29th under the direction of Prof. Sébileau and Prof. Dufourmentel. For details of this course application should be made to the Secretariat, Amphitheatre of Anatomy, 17, rue du Fer-à-Moulin, Paris.

The nineteenth French Medical Congress will be held from Oct. 11th to 14th, and amongst the subjects to be discussed will be septicæmias, the pathology of œdema, and the indications and therapeutic value of splenectomy. Particulars of membership may be had from Dr. M. Chiray, 14, rue Petrarque, Paris (16e).

A vacation course on the diseases of children, embodying the latest views, is to be held at the Hôpital des Enfants Malades, 149, rue de Sèvres, Paris, from July 25th to August 13th. Application for membership should be made to the Secretariat of the Faculty.

TYPHUS FEVER AT BRISTOL.

WE are indebted to Dr. P. Phillips, medical superintendent of Southmead Hospital, for the following particulars of a case reported in THE LANCET (July 2nd, p. 39):—

The patient was a woman, aged 32, a laundress at a large orphanage, and was admitted to Southmead Poor-law hospital, June 12th. On admission she was severely ill, and though able to talk could not give a definite account of her illness. Her condition might be described as a mild state of stupor, and she suffered from incontinence. There was a well-marked rash showing the three main elements usually regarded as characteristic of typhus, principally on the trunk, but also on the arms and legs. Deafness had set in since the commencement of the illness, the date of which was uncertain. Eyes, normal; cerebro-spinal fluid, normal; blood showed a leucopenia; agglutination tests (typhoid, paratyphoid A and B), negative; Weil-Felix reaction, definitely positive 1 in 125, weakly positive 1 in 250, on June 16th, and negative on June 28th.

Patient had apparently been ill for a week before admission to hospital. The temperature remained consistently high, with slight remissions, until a week after admission, when it fell to normal in 48 hours, after which she recovered rapidly. Pediculi capitis were found in small numbers; other pediculi were absent.

Contacts were watched for three weeks without result, and a careful search in the neighbourhood revealed no case resembling typhus, nor was there any history of association with persons or materials from abroad. The patient was seen by physicians experienced in the diagnosis of typhus fever, and was regarded as a doubtful case showing sufficient evidence to justify all necessary precautions being taken.

Public Health Services.

REPORTS OF SCHOOL MEDICAL OFFICERS.

COUNTY OF LONDON

THE magnitude of the work that has grown during the last 20 years in connexion with school inspection is shown in Dr. F. N. Kay Menzies's annual report for 1926. It deals with the health of over 650,000 London school-children during 1926, when 330,395 medical inspections were carried out and 258,638 children received treatment. The various sections into which the report is divided are written in vigorous style by the heads of the special branches of the service. Although great advances have been made in furthering the health and general wellbeing of the children, yet the work is still more remedial than preventive. As Dr. C. J. Thomas says in the report: "The School Service inherits children whose constitution has been already compromised." Entrants come to school with teeth just as carious as did their fathers; the proportion of entrant children with defects of the nose, throat, and ear shows little, if any, decline; enlargement of cervical glands and defective vision in young children are just as prevalent as they were years ago, and though gross rachitic deformities are now rarely seen, yet when Dr. Thomas applied Dr. G. C. M. M'Gonigle's (of Durham) criteria he found that the milder degrees of rickets can be detected in a much larger proportion of children than are reported by the medical inspectors. These small aberrations, perhaps unimportant in themselves, demonstrate the still large numbers of children whose general nutrition has been prejudicially affected long before school life begins.

Infectious Diseases.

Dr. J. A. Brincker calls attention to the practical disappearance of gastro-intestinal and insect-borne diseases such as cholera, typhoid, yellow fever and malaria, as well as small-pox. Unfortunately, preventive measures have scarcely as yet affected the incidence and severity of those diseases which are conveyed through the respiratory passages—e.g., diphtheria, measles, and whooping-cough, and those affecting the nervous system, such as cerebro-spinal fever, poliomyelitis, and encephalitis, all of which still exact a heavy toll of life and suffering among young children. He emphasises the value of active immunisation in combating the ravages of diphtheria, and states that vigorous research is being prosecuted in measles prophylaxis by the Ministry of Health in conjunction with the Medical Research Council, and he indicates the possibility of future effective anti-scarlatinal measures. The procedure of segregation at present adopted in London is outlined, with the measure of success that has attended it, but Dr. Brincker is convinced that the coöperation of the public must be secured to further these protective measures which are now being used with success in many parts of the world, and indeed in some parts of London. The experiment at Winchmore Hill for the residential care of cases of chronic encephalitis lethargica, although not producing the curative effects that were hoped for, has materially assisted in solving the problem of the disposal and treatment of such unfortunate children.

Feeble-minded Children.

Dr. F. C. Shrubsall traces the steps taken in London for dealing with feeble-minded children from the first tentative efforts in 1892—long before the work of Prof. Binet became known in England—until the present year, when 5517 children were statutorily examined for admission to mentally defective schools. He also contributes an excellent section in conjunction with Mr. Bishop Harman on measures for preventing blindness, indicates the methods adopted in London for providing higher education for myopes, and gives detailed instructions for the guidance of teachers in charge of them; lists of occupations open to and suitable for myopes are appended. The after-careers

of many children who have attended special schools have been tabulated and illustrate the excellent results of providing educational facilities for them.

Diseases of the Ear.—Rheumatism.

Mr. M. Yearsley, in his review of the special schools for the deaf, finds that the early treatment of nose and throat conditions has largely decreased the suppurative ear affections leading to deafness within the past 15 years, but cases of deafness following the non-suppurative conditions have not so decreased. Mr. A. G. Wells shows the good results of ionisation in the treatment of ear complaints. He describes a new method, known as "diastolisation," which, introduced by Dr. Gautier, of Paris, has now been used in London for treating cases of defective nasal respiration, particularly those due to hypertrophic rhinitis and the like. It consists of a to-and-fro movement of graduated hollow rubber bougies which are inflated and deflated while in the nasal canal. So far this method appears to have given good results.

Rheumatism in its various manifestations accounted for 24 per cent. of the chronic invalidity of the children, thus easily topping the list of disabling diseases. Yet it is the only widespread disease for the combating of which administrative measures are still lacking. However, a small beginning was made when the M.A.B. in November, 1926, opened 60 beds for acute rheumatism and 16 beds for subacute cases at Carshalton. The difficulty of securing cases in the acute stage is realised when we find that only 17 beds in the acute unit were filled by the end of the year, while all the subacute beds were occupied within a fortnight. An index of children suffering from subacute rheumatism was started in November, 1926, and on Feb. 25th, 1927, there were 1314 names on this list. It is obviously the insidious and protracted type of infection resulting in later cardiac involvement that specially calls for investigation and combined effort at prevention and cure.

Apart from the anthropological and optical surveys initiated by the Board of Education many original and painstaking investigations were undertaken by members of the staff. Dr. Thomas, reporting on the efficiency of the "plenum" system of ventilation in some of the older schools, quotes a letter written in 1912 from the then education adviser to the Council, Dr. W. Garnett, who with remarkable foresight suggested the existence of actinic rays which cannot penetrate glass and which might have a decided effect upon health. The efficiency of measures for safeguarding the health of the school population is exemplified by the fact that the nutritional standard of the London school-children was actually better in 1926 than it was in 1925, a remarkable result considering the widespread unemployment resulting from the industrial unrest prevalent during that year.

PORT SANITARY AUTHORITIES.

Dr. W. F. Dearden, in his twenty-first annual report to the *Manchester Port Sanitary Authority*, mentions that there was in 1926 no case of cholera, plague, or yellow fever. The number of cases of infectious disease actually dealt with at Manchester is not definitely stated, but two cases of enteric fever were taken to hospital. One case of tubercle died, one went to hospital, and three were treated on board, apparently on tramp steamers. Three cases of malaria and one of diphtheria were taken to hospital, and one case of measles in a child was treated on board a canal boat. On board ship 2344 rats were killed, 2656 ashore; 10 examined were free from plague; 26 ships were sulphur-fumigated, and the rats killed in each average 14. There were destroyed 600 tons of fruit from one cargo, ruined as the result of a single prolonged and hazardous voyage, also 10½ tons of frozen fish carried from Newfoundland as deck cargo. Besides these, 5½ tons of meat and 220 tons of other food were condemned. Among the 2102 vessels inspected, 546 (or 26 per cent.) had insanitary conditions; in 303 of these the defects were made good before sailing. There were defects in 22 per cent. of the foreign-going ships, 32 per cent. in coasting ships. The average crew appears to be one of 24 men. The most numerous defects were, forecastles requiring cleaning and painting (192), decklights, portlights, broken and defective (132), leakages into quarters (107), defects in water closets (91), in heating apparatus (39), in the water tanks (33). Of canal boats, 759 were inspected; 107 had leakages into cabins, 60 cabins were dilapidated and required repair, 42 required painting, 28 had bad or insufficient water storage, 38 were overcrowded, and in 21 the sexes were not separated.

In a letter introductory to his annual report to the *Cardiff Port Sanitary Authority*, Dr. R. M. F. Picken observes that the traffic of that year was the lowest for many years, owing to the coal strike; arrivals of vessels from May to November inclusive were about one-half the average. All vessels from foreign ports were inspected and 20 per cent. were found to have sanitary defects; two-thirds of the coasting ships were inspected and only 6 per cent. had defects. Fourteen cases of malaria came to notice, 7 of tuberculosis, 4 of pneumonia, and 1 each of diphtheria and typhoid fever; 10 other cases of tuberculosis were referred to their districts. There were no cases of cholera, plague, or yellow fever, and the hospital at Flat Holm Island, always kept in readiness, has been unused throughout the year. In all, 9159 rats and 1877 mice have been killed; none of the 266 rats examined was plague-infected. In ships were killed 2136 black, 43 brown rats; in warehouses 207 black, 50 brown. Fumigation by hydrocyanic acid has not yet been established here, though experiments detailed in this report have shown it is not deleterious to foodstuffs. Ship rats were more flea-infested than dock rats; *Ceratophyllus fasciatus* was more often found than *Xenopsylla cheopis*. Fewer fresh cases of venereal disease (the actual number was 565) appeared this year at the Seamen's clinic, but the reduction was far less than that in the tonnage entering the port. Nineteen seamen were treated at the corporation cleansing station for scabies and four for lice; the effects and quarters of the latter group were fumigated and cleansed. Bugs were reported from 101 vessels, and notices were served on the masters: vermicides were sprayed on berths, or were sent on board, for that purpose, and results were satisfactory, but sometimes the spray was used too little or not at all. None of the 291 aliens who passed through the port was refused entry. In 4473 ships inspected were found 52 dirty forecastles or bunks, 304 defective side lights or prisms, 140 had foul accumulations, 136 dirty w.c.'s, 101 verminous forecastles, 97 defective stoves. Water samples were taken from 253 vessels; 13 per cent. were bad. 1656 dirty and infected beds were destroyed. During the year there were "withheld from human consumption" 121 tons oranges, 9 tons potatoes, 51 tons wheat (only 0·03 per cent. of that imported), and 32 tons of apples. The sanitary condition of the canal boats proved satisfactory.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 9TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 185 (last week 228); scarlet fever, 1679; diphtheria, 763; enteric fever, 101; pneumonia, 777; puerperal fever, 36; puerperal pyrexia, 95; cerebro-spinal fever, 6; acute poliomyelitis, 8; encephalitis lethargica, 32; trench fever, 1; dysentery, 8; ophthalmia neonatorum, 115. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 8 (0) from enteric fever, 36 (1) from measles, 5 (0) from scarlet fever, 24 (2) from whooping-cough, 26 (7) from diphtheria, 38 (9) from diarrhœa and enteritis under two years, and 31 (5) from influenza. The figures in parentheses are those for London itself.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs. J. F. M. Campbell and R. Lyon to be Surg. Comdrs.

To be Surg. Lts.: H. J. Scott, T. S. Osborne, J. J. Keevil, and F. W. Gayford.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lt. J. L. Cox to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Capt. H. R. L'Estrange, half pay list, late R.A.M.C., on completion of a period of five years on the half pay list, retires on retd. pay on account of ill-health.

Capt. F. R. S. Shaw to be Maj., and remains secd.

The undermentioned Capts. to be Majs. (Prov.): J. H. Bayley and W. J. Robertson.

R. J. Monahan to be temp. Lt.

REGULAR ARMY RESERVE OF OFFICERS.

Col. C. J. O'Gorman, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Capt. J. G. Willmore, having attained the age limit, relinquishes his commn. and retains his rank.

Maj. W. Barclay, late R.A.M.C., T.F., to be Capt., and relinquishes the rank of Maj.

Maj. W. M. Mackay, having attained the age limit, is retd., and retains his rank with permission to wear the prescribed uniform.

Lt. W. H. G. Park, late Gordons, to be Lt.

Hygiene Companies: J. L. Turpie to be Lt.

Cambridge University Contgt. (Med. Unit) Sen. Div.: 2nd Lt. D. A. O. Wilson resigns his commn.

Supernumerary for service with O.T.C.: Capt. H. P. Malcolm (late R.A.M.C., T.F.), to be Capt., and to comd. the Med. Unit, Belfast Univ. Contgt., Sen. Div., O.T.C.

Capt. W. E. Le G. Clark resigns his commn.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. R. O. Ward, from Active List, to be Maj.

Capt. J. Steedman, from Active List, to be Capt.

ROYAL AIR FORCE.

J. Hill is granted a short service commission as Flying Officer for three years on the active list.

D. Loughlin (late Capt., R.A.M.C., S.R.) is granted a short service commission as Flight Lt. for three years on the active list.

Flight Lt. J. R. Crolius is promoted to the rank of Squadron Leader.

Flying Officer H. P. Sutcliffe (Temp. Capt., General List, Army, Dental Surgeon), relinquishes his temporary commission on resigning his commission in the Army.

The Duke of Connaught has appointed Col. Sir John Atkins, K.C.M.G., and Dr. Marcus Antonius Johnston De Lavis-Trafford to be Physicians in Ordinary to His Royal Highness in the room of Col. Sir Edward Scott Worthington, K.C.V.O., C.B., C.M.G., C.I.E., resigned.

Correspondence.

"Audi alteram partem."

DIET AND DIETISTS.

To the Editor of THE LANCET.

SIR,—We, the undersigned, wish to place on record our belief that the current statements that cancer, appendicitis, and many other diseases are the result of the use of white bread, are unwarranted, there being a complete absence of scientific data to justify them. Such statements are calculated to cause unjustifiable alarm in the public mind.

While we readily admit that vitamin B, which is essential to health, is present in wholemeal flour and practically absent from white flour, we do not subscribe to the statement that it is not contained in white bread, and that the use of white bread denies the human system the necessary amount of this vitamin. Not only is it difficult for a European to omit essential quantities of vitamin B from his diet, seeing that this principle is present in many other forms of food, but it is undoubtedly present in white bread also. The fact is that any lack of vitamin B in white flour is definitely remedied when the flour is made into bread by the addition of yeast, which contains plenty of it.

The importance of vitamins in the diet must not be allowed to obscure the necessity also for the requisite number of calories, which represent the energy or heat value of food so essential to all, and to manual workers in particular. Bulk for bulk, white bread yields more calories than any other form of carbohydrate food in daily use, with the possible exception of haricot beans. From economic considerations it is therefore better and cheaper for a family of limited means to continue to eat white bread rather than to change to another variety, which may or may not agree with them, and in any case would have to be consumed in larger quantities in order to give the same calorific value.

Important and frequently overlooked factors in the selection of a correct dietary are palatability and appearance. An article of diet which appeals to the eye and the palate by its appearance and flavour is more easily digested than one which is unattractive and not so well relished, even if it contains a more generous proportion of vitamins. This is a psychological aspect of digestion which has been recognised throughout the history of medicine and gastronomy, but entirely disregarded in certain recent propaganda.

One of the claims advanced in support of wholemeal bread is the fact that the bran of the wheat berry, which is excluded from white flour, provides the "roughage" stated to be essential because of its scouring effects on the intestinal tract. But most people obtain all the "roughage" they require from other foodstuffs; moreover, there are many individuals for whom this "roughage" is definitely harmful, and for whom it is a safeguard to eat white bread, which has no "roughage."

For the foregoing reasons we desire, in the public interest, to place on record that in our opinion:—

1. The case for wholemeal bread has been overstated.

2. The allegation that white bread is responsible for certain grave illnesses is not supported by scientific facts.

3. Although wholemeal bread is a good article of diet for many people, white bread of good quality is also a wholesome and nutritious food.

4. There are no good reasons for thinking that the substitution of wholemeal bread for white bread in the national diet would make for material improvement in the national health and physique.

We are, Sir, yours faithfully,

(Signed) GLADYS HARTWELL, D.Sc.,
Lecturer on Physiology, King's College for Women (Household Science Department), University of London.

THOMAS HORDER, K.C.V.O., M.D., B.Sc., F.R.C.P.,
Physician-in-Ordinary to the Prince of Wales.

S. G. MOORE, M.D., D.P.H.,
Medical Officer of Health, Huddersfield; Milroy Lecturer, 1916; Chadwick Lecturer, 1917 and 1923.

V. H. MOTTRAM, M.A.,
Professor of Physiology, University of London.

H. E. ROAF, M.D., D.Sc.,
Professor of Physiology, London Hospital Medical College, University of London.

T. B. WOOD, C.B.E., F.R.S.,
Drapers Professor of Agriculture, University of Cambridge.

To the Editor of THE LANCET.

SIR,—Sir Thomas Horder, in his recent MacAlister lecture, makes statements which are not in accordance with facts. Regarding the quantity of food, he states "there is no general consensus of opinion as to what

this requirement in calories actually is." The subject is not one about which "opinions" can exist. Calorimetry is an exact science, and the calorie requirements of individuals under various conditions, whether engaged on physical or mental work, have been accurately measured. It is unfortunate that Sir Thomas Horder is "unimpressed" by data obtained by precise methods. There is no doubt about the accuracy of the data. During the war the Royal Society issued a report upon the average calorie requirements of men and women of diverse occupations, and the practical value of these figures was proved by their successful use in the rationing of the fighting forces and of civilians. The best account of this work is given by the late Prof. E. H. Starling in the "Feeding of Nations." In everyday life such calculated economy of calories is not necessary, and the tendency is to eat rather more than is actually needed.

As to the comparative calorie values of wholemeal and white bread, both kinds give an average of about 1000 calories per pound, variations being due to differences in the water content. As to the amount of fibre, white bread has from 0·2 to 0·5 per cent., and wholemeal from 0·5 to 1·5 per cent. The difference is not great, and this small percentage of fibre cannot adversely affect normal digestion.

The question really at issue is in respect to the quantity of vitamin B in these two kinds of bread and in the diet as a whole. The addition of yeast to white flour in the baking of bread is not overlooked by scientific workers, but the point is that not enough yeast is added to compensate for the loss of vitamin B from the whole grain in milling. Ten per cent. of baker's yeast is needed to make good the loss, whilst bread, as usually baked, contains from 1 to 2 per cent. As much white flour is consumed in the form of cakes, pastry, puddings, &c., in which there is no yeast, as is consumed in the form of bread. The argument that "it is of very minor importance" as to whether we use wholemeal bread or not because "other common foods—namely, eggs, peas, beans, lentils, and nuts are very rich in this same vitamin"—is fallacious. The quantity of B-vitamin in these foods and the quantity of these foods actually consumed is disregarded by Sir Thomas Horder and others. If the quantities of these foods, which are eaten, are actually measured, it will be found that we do not eat enough of them to compensate for the absence of vitamin B from white flour, sugar, chocolate, fat, and meat.

The actual quantity of vitamin B in any foodstuff cannot yet be measured directly, but the minimum quantities of the various foodstuffs needed to supply enough vitamin B for health have been determined by Dr. Harriette Chick at the Lister Institute and also by my own experiments. I have found that the B-vitamin requirement could not be measured in terms of a daily dose, but that the supply must be proportional to the total calorie consumption. The vitamin-B value of various foodstuffs was estimated by feeding experiments upon birds and rats, and the applicability of the results to man has sometimes been questioned. We know, however, the proportion of whole barley required in the ration to prevent beri-beri in the Japanese Navy, and find that this corresponds with the requirements of birds. To provide enough vitamin B in a diet otherwise devoid of it, at least 40 per cent. must consist of wholemeal or some equivalent foodstuff, such as pulses or nuts. In most households these foods are seldom used and then only in *small* quantities. To get enough from eggs, the commonest daily foodstuff apart from cereals, it has been found that almost half the diet must consist of the yolk. Green vegetables and fruits contain very little; potatoes are better, but must be eaten in the proportion of 9 parts of potato to balance 1 part of white flour or sugar, &c.

Reviewing the average daily consumption of all the foods supplying vitamin B in the ordinary mixed diet, the total is not sufficient to balance the white flour, meat, sugar, and other foods devoid of vitamin B. The easiest and cheapest way to ensure enough is to use nothing but wholemeal flour in all bread, cakes, puddings, &c. The other alternative, if white flour is preferred, is to include some food very rich in vitamin B, such as dried yeast in an amount equal to 4 per cent. of the whole diet, or wheat germ equal to 6 per cent., or marmite equal to 10 per cent. These are the minimum quantities. It is well known that *absence* of vitamin B leads to beri-beri, which is seldom or never seen in this country. McCarrison has pointed out that the early stages in the disease are digestive and heart troubles. The symptoms found in my animals and birds on too little vitamin B were dilated heart, intestinal stasis, swollen appendices. These symptoms are more fully described in the recent and important paper by Dr. M. J. Rowlands. On the shortage of vitamin B these symptoms are chronic instead of being the early stages of beri-beri. They are the common everyday troubles from which many people suffer, and their cause is most probably from a shortage—i.e., too little—vitamin B.

This is the crux of the food question at the present time. There is no doubt that the daily food contains too little vitamin B. Do we get enough of the other vitamins? In many cases there appears to be too little vitamin A and D as evidenced by rickets. Do we get ample vitamin C? Probably most people do, as the fresh fruit and vegetable consumption is fairly large. These points are not considered in Sir Thomas Horder's lecture, but are of importance in the study of dietetics.

I am, Sir, yours faithfully,

R. H. A. PLIMMER.

St. Thomas's Hospital Medical School,
July 16th, 1927.

To the Editor of THE LANCET.

SIR,—I read with much appreciation Sir Thomas Horder's lecture on this subject in your last issue, and I congratulate him on the sanity of his views and the clearness and common sense of his expression of them.

I know of no advantage possessed by wholemeal bread over white bread except its possible "scouring" action on the mucous membrane of the colon, and even such mechanical irritation of a mucous membrane is probably a disadvantage, owing to the constancy of the irritation and interference with assimilation. On the other hand, there are two disadvantages possessed by wholemeal bread as compared with white bread which were presented in evidence given before the Departmental Committee of the Ministry of Health on the Treatment of Flour with Chemical Substances, of which committee I was a member. The reference of the Minister of Health to that committee did not convey any instruction to inquire into or report on the relative advantages or disadvantages of the various forms of bread, but incidentally evidence was given bearing on this point. One piece of evidence was to the effect that the preference for white bread among hard manual workers (which was in existence before the artificial bleaching of flour commenced) is probably due to the production after consumption of more calories per pound in the case of white bread than in that of wholemeal bread. Experiments had shown that 1250 calories were produced from a pound of white bread made with patent flour, and only 1050 calories from a pound of wholemeal bread. The main difference between the two breads is that the less digestible matter of the wholemeal flour is taken out in order to produce white bread. The other disadvantage of wholemeal bread is an economic one in that it contains 8 to 10 per cent. more moisture than white bread, so that the consumer is paying for that 8 to 10 per cent. of extra water at the price of bread. This roughly means that for every £11 paid for such bread £1 is being paid for the additional water.

I welcome Sir Thomas Horder's remarks on the question of colonic stasis as much as I deplore the campaign of propaganda in connexion with that nebulous idea.—I am, Sir, yours faithfully,

Limpsfield, July 16th, 1927. ARTHUR P. LUFF.

To the Editor of THE LANCET.

SIR,—Everyone will agree with Sir Thomas Horder in deprecating extreme or personal views in attempting to educate the layman in matters of health, nor will one grudge him his obvious enjoyment in laying out the uneducated "faddist" even though so easy a victory be deemed unworthy of so skilled a swordsman. Unhappily he has succeeded, I trust unwittingly, in conveying the very strong impression that in his opinion (and it is an opinion which carries no small weight with the public) there is no necessity for any concern as to the dietary habits of the bulk of the population.

It is common knowledge that over-eating is the prevalent dietetic fault in the class which is in a position to frequent the consulting-rooms of the West End of London. If more moderation and common sense were exercised by the well-to-do there would be little fault to find in their dietary, since the variety of their foodstuffs insures them against any serious deficiency. But they represent a mere fraction of the community. For the great bulk of the people the *integrity* of their staple foodstuffs, strictly limited as they are in quantity and variety, is of vital importance. It is no use begging the question and, having taken for granted that everyone gets a "wholesome and mixed diet," pointing out a few directions in which they may go wrong on it. The average dietary of the millions who subsist on incomes of less than £250 a year is neither wholesome nor sufficiently varied.

Sir Thomas Horder's quibble about vitamin B in white bread is unworthy of him and is utterly discredited by the majority of dietary experts. It is not, they tell us, the actual quantity of this vitamin consumed that matters, but the ratio that quantity bears to the total food taken. The amount of vitamin B in white bread is very small, and it does not serve to balance the starch consumed with it. The correct balance is to be found in nature's unspoilt product. Nor is the deficiency compensated for in the average dietary by the use of expensive eggs or by the very limited amount of lentils, peas, beans, and nuts which appear in the poor man's dietary. One would think that wholemeal bread is a novelty in human experience. It is white bread that is the innovation. If the cellulose of whole cereals is so disastrous in its effect it is surely remarkable that man has survived his machine-less past.

Sir Thomas Horder says that there are few established facts as to the connexion between diet and disease. It would be nearer the truth to say that there are few better established facts in our knowledge of the causation of disease. The public will continue to form its own ideas as to the wholesomeness of their diet until it is educated as to the real meaning of the word. Scoffing at the extremist will only serve to encourage ignorance and self-indulgence.

I am, Sir, yours faithfully,

S. HENNING BELFRAGE.

Gloucester-place, W., July 16th, 1927.

DIPHTHERIA IN LONDON.

To the Editor of THE LANCET.

SIR,—Whilst Mr. Maben recognises agreement on the published facts of diphtheria incidence and mortality in London, we differ materially as to their significance and in our respective points of view—namely, the need for prevention and the efficacy of treatment. The latter is not in question, and all reference to it was purposely avoided in the compilation of my report, the burden of which was and is prevention.

Mr. Maben's plea in mitigation of London's diphtheria record encourages an attitude of complacency in the face of evidence which cannot be ignored, however fully reliable antitoxin treatment may be, if promptly enough applied, in bringing about a decline in the case mortality.

The following facts stand out in the diphtheria records of 1925 and 1926, (1) that in England and Wales some 5500 children under the age of 15 years died of diphtheria (about 2800 under the age of 5 and 2700 between the years of 5 and 15); (2) that in the metropolitan area of London, with its population one-eighth to one-ninth that of England and Wales, over 1000 children under 15 years died of diphtheria, accounting for nearly one-fifth of the England and Wales mortality. (Of these about 600 were under 5 years and 400 between the ages of 5 and 15); (3) that in the school age-group of 5 to 15 years the number of deaths due to diphtheria alone outnumbered the combined mortality from measles, scarlet fever, and whooping-cough by over two to one.

These facts call for publicity rather than the allaying of anxiety in the desire to tone down the "degree of blackness" in London's record.

As regards the means of prevention by T.A.T. immunisation at present being made use of in London, it may be stated that, although prophylactic inoculation against diphtheria, provided in the City of Westminster and boroughs of Holborn, Camberwell, and Deptford (and in Greater London, Willesden, Tottenham, and Hornsey), is meeting with decidedly encouraging response from parents, and similar facilities have lately been made available in Battersea, these five out of the 29 metropolitan boroughs represent only about one-eighth of the London population, and there are a number of other boroughs, notable for higher diphtheria rates and greater overcrowding—e.g., Bermondsey, Bethnal Green, Shoreditch, Southwark, and Stepney, where, though more needed, no such preventive measures have yet been adopted.

I am, Sir, yours faithfully,

J. GRAHAM FORBES.

County Hall, S.E.1, July 18th, 1927.

A DISCLAIMER FROM PROF. STEINACH.

To the Editor of THE LANCET.

SIR,—A medical colleague in London has sent me a copy of an advertisement which appeared in several London journals, headed "Rejuvenation of Facial Beauty and Bodily Energy," in which the Dr. Frederick Heymann Institute misuses my name. May I, through your columns, make it clear that I have no interest in this institute and no personal acquaintance with anybody connected with it, and that I desire to protest most strongly against this unauthorised use of my name?

I am, Sir, yours faithfully,

EUGEN STEINACH.

The University, Vienna, July 7th, 1927.

THE LATE DR. JOHN PURCELL.—Dr. John Purcell, who died on July 11th in his seventy-second year, was educated at Queen's College, Cork, and Dublin, and qualified L.R.C.P. and L.R.C.S. Edin. in 1878. Some 40 years ago he settled in practice at Silsden, near Keighley, Yorkshire. He took a prominent part in the sporting life of the town, and it was largely due to his enterprise that in 1883 there was formed the Silsden Football Club of which he was president. He was also an enthusiastic member of the Craven Harriers. Dr. Purcell leaves a widow, one son, and five daughters.

TUBERCULOSIS IN CARNARVONSHIRE.—In a return made to the Carnarvonshire County Council, the medical officer of health, Dr. Parry Edwards, stated that tuberculosis accounted for 200 deaths annually in the county, and that there were approximately 900 cases of pulmonary tuberculosis on the registers of the medical officers. In some districts the death-rate showed no appreciable improvement during the last 20 years. A considerable number of the cases examined and recommended for hospital treatment did not avail themselves of the facilities offered. There were 63 unnotified cases among the deaths in 1926.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

COMPENSATION FOR IMPROVEMENTS TO PROFESSIONAL PREMISES.

DURING the discussion of the Landlord and Tenant (No. 2) Bill by Standing Committee B of the House of Commons on July 12th, the question of applying the provisions of the Bill to professional premises, and particularly to doctors' premises, was raised.

An Amendment.

Sir RICHARD LUCE moved to insert in Subsection 1 of Clause 12, after the word "business," the words "or profession." He said that he understood that the Government did not intend to oppose this amendment if there was a definite expression of opinion on the part of a considerable number of people that the provisions of the Bill should extend to professional premises. He desired to speak specially of the medical profession. There was a considerable body of opinion in that profession in favour of being included. The British Medical Association had passed a resolution to that effect without any opposition, and the Medical Practitioners' Union had done the same. There was also a considerable demand from dentists to be included, and he was glad that the Government through the Home Secretary had promised that this matter should be left to the free vote of the Committee. There was really no difference between the relation of a doctor or a dentist to his professional premises and the relation of a tradesman to his shop. A doctor depended on the premises where he did his work, and if he was turned out or lost his goodwill it was just as important to him as to a shopkeeper. A doctor might have to improve his premises for professional purposes. He often had to build a garage solely for the purpose of his practice, and in other cases he had to build premises under the direction of the Insurance Act Committee to provide suitable accommodation for his patients. Such an improvement must inevitably be of value to the house in letting it to a doctor on another occasion. Therefore it seemed to him that there was no reason why professional premises of this kind should not be added to the Bill in the same way as shops and business premises.

Mr. MACLAREN said he was sure that the Home Secretary would agree that there were certain people who might be termed professional men who would suffer severely under the strict lines of the original Bill. He therefore wished to support the amendment.

Goodwill and Compensation.

Sir P. PILDITCH said he hoped that both the Home Secretary and the Committee would be careful in giving support to this amendment, because it meant a very large extension of the Bill. The speeches made in its favour had referred mainly to doctors, but what he intended to say applied not only to doctors, but much more largely to other classes of professional men. He did not know whether the amendment would open the door to professional men getting compensation for material improvements made, or whether it would open the door to the whole question of compensation for goodwill. There was something to be said in the matter of improvements, but nothing with regard to the whole question of goodwill. The theory that it was possible for a professional man to have acquired the class of goodwill which this Bill was going to cover was absurd. The goodwill that was to be compensated for under this Bill was goodwill which remained appurtenant to the premises. Could anyone imagine that any doctor, or other professional man, could possibly have created goodwill which he could not take away with him when he left the premises? He did not think that the great extension which this amendment would bring about was justified, because it would do away with the real intention and meaning of the Bill, which was never meant to extend to private residences. They found many cases of houses in Harley-street where three or four doctors carried on their profession. The same applied to Wigmore-street, or to Finsbury-square or Finsbury-circus in the city, where there were great blocks of buildings full of doctors. Every one of them would have a claim, if this amendment were adopted, for compensation not only for improvement but also for goodwill, and they would get a set of circumstances which would make the work of the tribunal almost unthinkable.

Mr. CRAWFURD said he thought that Sir P. Pilditch had excelled himself in his speech on this amendment. He began by complaining that it would, if adopted, greatly extend the scope of the Bill. If the Bill was a good Bill why should they not extend its scope to the greatest possible numbers? Sir P. Pilditch seemed to him to have advocated a very dangerous principle. He said that the Bill was originall intended to help retail shopkeepers, and that it was a pit to extend it beyond that. What a vicious thing that wa to enunciate! Surely the Committee was not sitting t help particular classes of people, but to establish certai principles of law, and if more than one class came under th same principle surely it should be extended to those classe as well. What was the difference between the position o the professional man, such as the doctor, and the reta shopkeeper in respect to this principle?

Mr. G. JONES said that if it was right that a man wh spent money on improvements should be compensate and that a man who built up a goodwill should also b compensated, he could not see why they should not exten that principle to the professional man in the way suggeste in this amendment. They were trying to help doctors an other professional men and to prevent them from bein victimised in the way that tradesmen had been victimise in the past. Suppose a doctor built a surgery. It might b that the surgery would be quite useful for residentia purposes, and if the landlord could get the doctor ou probably he would be able to obtain an increased ren In such circumstances why should the doctor not be com pensated for the improvements he had made to the premises He hoped that the amendment would be accepted.

Mr. WOMERSLEY said that his invariable experience ha been that when a man required certain premises for profes sional purposes the owner asked more rent than he woul charge to a private resident. He had handled many suc cases, in which there had been a row of houses, and whe a doctor came along looking for premises to carry on h profession the rent had been put up against him. In thes cases the owners realised that they were at liberty to charg more rent. He contended that the doctor or the dentist ha a right to be compensated to such an extent as the tribun might decide. It had been said that a professional ma could take his goodwill away with him. Generally speakin he did not think that a doctor or a professional man cou take with him the goodwill attaching to his premises. I should support the amendment.

Sir M. MANNINGHAM-BULLER said that no definition ha been given of a profession. The profession of a doctor w one in which there was a very strong case for compensati for improvement. In regard to the question of goodwill connexion with the medical profession, an entirely ne outlook was required as to what was a doctor's goodwi Was the practice which a country doctor bought to looked upon as goodwill? If the doctor was unable to g a fresh lease was he to get compensation for what he h paid for his practice? He thought that that was a vi that some doctors were inclined to take. But if, in a count district, a landlord knew that if he let premises to a doct he might be rendered liable to pay him the whole of t amount that he paid for the practice, the doctor would fi it very difficult to get a house. If the whole of the professio were going to be embraced in the Bill consideration wou have to be given to the many different and conflicting vie as to what the goodwill of a doctor, or possibly an auction or surveyor and so on, might be. If the amendment w one to allow the payment of compensation for improveme made by such people as doctors and dentists, it would ha his support. If, however, it opened up the question of co pensation for all the various degrees and forms of goodw throughout all the varying professions, which were not e yet defined, they would very likely overload the Bill a make it unworkable. If that were to be the result of supp of the amendment he should vote against it.

The Home Secretary's Amendment.

Sir W. JOYNSON-HICKS said that he would not ask Committee to decide one way or the other on the term the amendment, but he would put his views before Committee. He thought that the amendment cle brought all professional men, both for improvements for compensation, within the scope of the Bill. That carrying the Bill considerably further than they had hitherto. Having been a professional man himself fo good many years, he thought that the type of goodwil a professional man's business, so to speak, was not the s as in a tradesman's business. He had moved from one of London to another and it had made no difference to value of his goodwill. In the Bill they were not dealing the goodwill of the tenant, but with the pecuniary advan which the landlord got at the end of the tenancy by fact that a particular trade or business had been carrie in the house in question. He did not think that the that he had carried on the profession of a lawyer or R. Luce the profession of a doctor in a particular house really going to bring many more patients or per desiring legal advice to that house after the lease was if another doctor or lawyer took it. Therefore the land would not get very much advantage from the fact that

business of a lawyer or doctor or sculptor had been carried on in the premises in question. It would be complicating the Bill very much, and would make it very much more difficult, to go into all these questions as to what the landlord had received by reason of the fact that a lawyer, doctor, or sculptor had carried on his profession in the particular premises. In regard to improvements there was more to be said for the proposal in the amendment. A doctor in premises in the country might want to put up a garage; or a panel doctor in the East End of London might think it necessary, owing to increase of business, to enlarge his surgery. He thought that that was just as much an improvement in business premises as when a tradesman desired to enlarge his shop front, and so on. As representing the Government he did not propose to take part in the division on the amendment, but he wondered if Sir R. Luce would accept a suggestion from him, and whether they could all unite to give professional men something, but perhaps not quite all, that they asked for. If the amendment were pressed to a conclusion there was likely to be a strong division of opinion, and the matter might ultimately have to go downstairs to the House to be fought over again. He wondered if they could get out of the difficulty by confining the idea underlying the amendment to the earlier part of the Bill by adding, at the end of Subsection (2 *b*), these words:—

"Provided that, so far as this part of this Act relates to improvements, premises used for carrying on a profession shall be deemed to be premises used for carrying on a trade or business."

That would go a long way to meet the views of the doctor or even the sculptor, and would be a reasonable amendment. If it were generally accepted by members who opposed altogether any extension of the Bill and by those who wanted to extend it further, he thought that it would certainly be accepted by the medical profession, and that the House of Commons would say that the Committee had come to a wise and sensible decision in the matter.

Sir G. HOHLER said that the amendment was clearly inconsistent with the language of the Bill which had already been passed. The language of Clause 4 in regard to the goodwill of a trade or business was quite inapplicable to the profession of a doctor or surgeon or solicitor or barrister. Hitherto they had only dealt with trades and business, but they were now being asked to extend it to the professions. They were now extending the Bill to every private residence, which was not the object of the measure. If the amendment were accepted the gravest difficulties would arise. A landlord would be called on to pay goodwill to a doctor. What would be the value of that goodwill to him? The landlord would never know what he had to pay.

Sir R. LUCE said that he could not quite admit that there was no goodwill in the case of the professional man. In certain circumstances there was goodwill arising out of the place itself, and quite apart from the goodwill of the doctor which had been built up by his professional ability. A doctor might settle in a place and convert a house into a place which became well known as a doctor's house. In many cases those houses went on from generation to generation. But after what the Home Secretary had said he was prepared to leave the matter in his hands entirely. On the understanding that the Home Secretary would move the amendment he had indicated, he (Sir R. LUCE) would withdraw his amendment.

Sir R. LUCE'S amendment was accordingly withdrawn.

Sir W. JOYNSON-HICKS then moved the amendment which he had outlined in his speech. He said that the wording might be a little awkward and it might be necessary later to pull the clause together a little. But, at any rate, the amendment brought a profession within the scope of the Bill. He regarded it as a compromise. He took it that the Committee would be prepared to accept it as a whole, though he did not want to force it in any way.

The amendment was agreed to.

PENSIONS ADMINISTRATION.

ON Wednesday, July 13th, the House of Commons went into Committee of Supply on a vote of £38,242,832 for the salaries and expenses of the Ministry of Pensions, Captain FITZROY, Deputy Chairman of Committees, in the chair.

Lieut.-Colonel STANLEY, Parliamentary Secretary to the Ministry of Pensions, said the total sum for which they were asking to carry on the administration of the Ministry this year was £61,442,000, which was still the largest vote submitted by any one minister. This sum represented a reduction of rather less than £2,500,000 on the estimated expenditure for the previous year, and it was the smallest reduction that had been proposed on any of the Ministry's estimates up to the present time. The largest proportionate item in the reduction was in respect of administrative expenses, which had been reduced by 10 per cent. compared with last year. On the other hand, the expenditure on benefits would be reduced by only 3½ per cent. The administrative cost of the medical services would be £298,700. The administrative expenses now only amounted to 2½ per cent. of the total vote. They were now within sight of the limit in reduction of the amount of money spent on administration compatible with the efficient working of the Ministry. The total staff of the Ministry all over the country, numbering 9130, included 2741 officers belonging to the medical services—doctors, hospital nurses, orderlies, and clerical officers engaged wholly on medical work—and it included 2486 in the local area offices of the Ministry all over the country, some of whom also were engaged on medical services. On the benefit side of the medical services the amount which they were asking for in this estimate was £2,507,500, a decrease of 8 per cent. on last year's expenditure. Nearly one half of the cost of medical treatment was due to mental cases, which remained fairly constant. The decrease over last year was due to diminishing need for hospital treatment. The vast majority of surgical cases especially had had all the treatment they needed, or could need now, but, of course, there still remained a certain number of cases where the ailments were liable to recur. For those cases it was obvious that they must still retain hospital accommodation, but the number was diminishing, though the necessity for retaining the accommodation would remain for some years to come. On the whole, the hospital population of the Ministry was declining, as it was bound to do. They calculated that this year there would be an average number of in-patients of 14,000 of all classes of cases, medical and surgical, as compared with 15,000 last year. The death-rate among disabled officers and men was slowly though very slightly becoming lower. On the other hand, the deaths among dependents had increased.

Reduction of Vote Moved.

Mr. F. O. ROBERTS (Pensions Minister in the Labour Government) moved to reduce the vote by £100. He said that with regard to the question of treatment he felt a little disquieted at the number of complaints which had reached him and other members of the Committee. They found from the estimates 9400 more patients would probably be treated by their panel doctors or private practitioners. That seemed to him to be a particularly large estimate, and one that could work very unfairly indeed, because a man, though totally incapacitated from work, might find himself deprived of any allowance at all. The Ministry had set up a staff of permanent medical officers and advisers, but if this policy, which now seemed to operate as far as treatment was concerned, was carried to its logical conclusion, it meant that ultimately every ex-Service man who claimed treatment allowance would be sent to his panel doctor or to a private practitioner, and there would be nothing left for the Ministry's doctors to do for them. He hoped that the Minister would be able to disabuse his mind of that fear. A provision was made under another head for sickness grants, and £2000 was allocated for that purpose. There were some 377,000 widows, and children of widows, and the percentage of sickness which must obtain amongst them must be fairly high. He wondered whether £2000 was a sufficient allowance to make in order to meet the legitimate requirements of those who might be affected in some particular way, and he would like to be assured that proper provision was being made so far as sickness allowance was concerned.

The Seven Years' Time-Limit.

Major COHEN said that the British Legion had been pressing the Government for some time about the seven years' time-limit, and the Minister now was able to revise cases which were brought to his notice by exercising his discretion. He thought that the right hon. gentleman did exercise his discretion on many occasions, but there was a tremendous difference between discretion exercised by a minister, however sympathetic, and a statutory right. Great Britain, so far as the time-limit was concerned, was behind other countries and the Dominions. He thought South Africa had no time-limit. Canada had a seven years' time-limit, but any record disablement through service was considered as equivalent to an application for a pension. If a man in the Canadian Army during service suffered from bronchitis and went to hospital, and if at any time during his lifetime he suffered from bronchitis arising out of it, he was entitled to put forward a claim for pension. Australia had no time-limit. France had a five years' limit, but they extended it to Dec. 31st, 1928, and they might extend it further. In regard to Germany, he could not find out whether they had a fixed time-limit or not, but he was given to understand that a man could lodge a claim within any period, and if it was turned down he had a right to go to a higher tribunal. America had extended her time-limit so far as tuberculosis cases were concerned. It was particularly in regard to tubercular cases and cases arising from gas poisoning that the British Legion pressed forward this revision. The Legion had its own home for men suffering from tuberculosis at Preston Hall, near Maidstone, and they

were there experimenting to see what was the effect of poison gas on the lungs. Such cases as those might occur well outside the seven years' limit. It seemed to him that it was particularly in cases of tuberculosis and illnesses arising out of gas poisoning that the seven years' limit was quite likely to fail. He asked the Government whether they could possibly reconsider the question of altering the limit, at any rate so far as the men he had referred to were concerned.

Difficulties in Assessing Final Awards.

Dr. DRUMMOND SHIELS said in the case of final awards for those under 20 per cent., where there was no permanent pension, the point had been made over and over again that it was impossible for any medical man, or any body of medical men, to say that in 52 weeks, or in 104 weeks, a man's condition would be such that it could be met by a certain money payment, and that thereafter the obligations of the State were ended. That was quite impossible, and they claimed that Circular 30, which they had to work at the present time, was a very difficult procedure. Another difficulty existed in connexion with these cases. A man went for treatment and he was told that his condition was such that treatment by a panel doctor was quite sufficient. The panel doctor might certify that the man was unfit for work altogether, and it seemed as if in many of these cases there was a rather mean attempt to save the allowances to which the man was entitled. They ought also to give a right to every man to a revision of his case on the certificate of a medical man. The Ministry did not show that respect to the certificates of either panel or ordinary medical practitioners which they ought to show. The Ministry would not accept, or sometimes even consider, any outside medical opinion. He did not think they had any justification for that attitude. It was quite obvious that where men since the war had suffered from malaria, bronchitis, and various other diseases, and were in a low state of health, they were more susceptible to any other illness. In their cases ordinary ailments tended to take a more serious form, and they ran much greater danger of death. Why should a rather mean discrimination be made when death was not wholly due to war disability? He had always felt that the Ministry in this matter did not realise the wishes of the British public. He felt that here, as in all these pensions regulations, the decent man was always penalised in comparison with the man who ran to the dressing station or into hospital on the slightest provocation and had therefore the best medical history sheet.

Tuberculosis and War Service.

Mr. MORRISON said that some ex-Service men who had experienced long periods of unemployment and had only a small disability pension were unable to get proper food, they developed malnutrition, and some of them finished up in a sanatorium suffering from tuberculosis of the lungs. When that happened—and he had known quite a number of these cases—they were refused a pension in respect of tuberculosis, although they might be getting a disability pension in respect of a wound. The officials of the Ministry contended that the tuberculosis had been neither caused by nor aggravated by war service. If a man who had been out of work for years because of his disability and who had been slowly starved, developed tuberculosis of the lungs, surely the Regulations of the Ministry ought to be wide enough to say that that man's disability had arisen indirectly from war service.

Major HILLS said he had quotations from letters in 232 cases, all from soldiers who had received the light metal legs. They were mostly cases of amputation below the knee, and they all expressed the very great benefit which the light metal leg had given to them. One of these soldiers said in his letter: "I wear the leg all day without pain. It is 2 lb. lighter and I do not get the heavy drag of the old wooden leg." Another soldier wrote: "All trouble ceased with the wearing of a metal leg, and I have a better pull on life. My walking efficiency has increased by 100 per cent." He (Major Hills) hoped in future that soldiers would be given a choice in all these cases and would be allowed to have the light metal limbs if they wished to have them.

Widows' Pensions.

Mr. NAYLOR said that several cases had come to his notice of widows who had been unable to claim a pension on the death of their husband because the death certificate showed that the pensioner died from a disease other than that in respect of which he received a pension. He did not want to enter into a disquisition upon the weaknesses of the medical profession, but some of them had reason to believe that doctors were not always meticulously careful when they entered their names on death certificates. He had two cases brought to his notice in which the circumstances appeared to him to be extremely doubtful. In each case, because the death certificate showed that the man had died from a disease other than that in respect of which he had been pensioned, the widow failed in her claim. It seemed to him that the Minister might exercise a little closer supervision in the matter of these certificates issued by hospital doctors. He suggested that the Minister might consider the advisability of issuing a circular asking doctors in hospitals when they had to certify the death of pensioners who had been under the care of panel doctors to consult with those doctors before signing the certificate, and to be extremely careful as to how they signed away the rights of a widow to claim a pension. The number of such cases was very large throughout the country. Many men whose physical condition had deteriorated to an extent which incapacitated them for work had told him that they had been refused the assistance they asked on being sent to a military hospital. It seemed to him that the doctors of the Ministry of Pensions who examined these men very rarely gave them the benefit of the doubt, and many a man had suffered by reason of his not getting the best possible treatment because he was unable to get treatment without getting rest from his employment. They struggled on because they could not afford to be sick. He suggested that the Minister might consider the advisability of allowing these men to go to a military hospital and secure the treatment allowance which would enable them to get well enough to resume their employment.

Discretion in Reopening Neurasthenia Cases.

Sir W. GREAVES-LORD urged that the Minister should consider the question of exercising discretion in reopening cases of neurasthenia. The difficulty of rigid regulations in matters of this kind was largely this, that medicine was not merely not an exact science, but medical men were constantly revising their standards. They were constantly finding out that their practice had been mistaken and that the origins of disease were very much further back than they thought they were. He did not think there was anything in which this was more marked than in connexion with neurasthenia. It might come on soon after circumstance which gave rise to disability; it might come on as part of a very long history, sometimes apparently disconnected and when it did come on in that way it was infinitely worse from the point of view of disabling the sufferer. He was not quarrelling with the decision, but he did bring before the Minister of Pensions recently a case where a member of the medical profession of great renown expressed the very definite view that neurasthenia quite incapacitated a person for work. In the case of a servant of the London County Council the opinion of Sir John Collie was that he was suffering from neurasthenia as a result of war service and disabilities received in war service. Yet that case was apparently one which could not be reopened. He thought where medical men themselves could not set up any exact standard, it was going very far indeed for a Government department to try to set up an exact standard for them. He hoped it might be possible, particularly in cases of neurasthenia, to exercise a wider discretion in reopening cases of that kind.

Reply of the Minister of Pensions.

After further debate,

Major TRYON said that as a matter of fact the wooden limb was lighter than the light metal limb. So far from the former limb being condemned they had medical reports from various limb-making centres bearing out the statement that the wooden limb, besides being lighter, required less repair. In any case the surgeon decided which was the best limb in each particular case. No part of the work of the Ministry had been more difficult, had received more attention or had been more desperately trying to the medical staff engaged on it, than the work of caring for mental cases and neurasthenics. He paid a visit a few weeks ago to a new modern hospital at Cobham in good surroundings. In that hospital they had about 500 neurasthenics and were doing their best for them. There was also Edenhall, near Edinburgh, with nice grounds, and there was a beautiful hospital at Erskine House on the Clyde. Close to London there were two or three very charming houses and grounds in which these men were being treated. As to the seven years' limit, he would remind the Committee that that was the unanimous decision of the House of Commons and it has been maintained by successive Governments. It was true that in some other countries a shorter period had been adopted, but experience seemed to suggest that our period was the right one. On the question of final awards he would point out that all through the demand had been for security for the ex-Service men. They did not want to be examined or go before medical boards; they wanted to be left alone. The main point was that under the system final awards over 300,000 men had secured absolute protection against any reduction of their assessment by medical boards for the rest of their lives. That was a great benefit for these men.

Progress was reported and the debate was adjourned.

HOME OFFICE AND INDUSTRIAL DISEASES.

On Thursday, July 14th, the House went into Committee of Supply on a vote of £257,647 for the salaries and expenses of the Home Office, Captain FITZROY, Deputy Chairman of Committees, in the chair.

Mr. RHYS DAVIES said there were about six million workpeople engaged, and their safety in their miscellaneous occupations was in the hands of the Home Office. There were every year nearly 1000 fatal accidents and approximately 170,000 non-fatal. Were it not for the law and the enforcement of certain regulations the figures would be more alarming. The Home Office had a factory inspectorate of 207 persons, and he wished to be assured that that staff was sufficient. Unfortunately the number of fatal and non-fatal accidents was not declining at a proper rate, and they had a right to protest against apathy of the public and of the Home Office. How far would the Home Secretary carry the propaganda in factories in favour of "Safety first"?

Mr. TINKER, in reference to the Order of July 1st in regard to the Workmen's Compensation Act, quoted the Order: "Subcutaneous cellulitis over the patella (miners' beat knee) and acute bursitis over the elbow (miners' beat elbow) is revoked, except as regards cases arising before the commencement of this Order," and said that the Home Secretary had extended it to include bursitis of the knee, but the inclusion of the word "acute" was unfortunate. A miner was on his knees most of the time, and bursitis was likely to arise. But under this Order it had to be acute before a man could get a certificate. The policy of the House was always to treat disease and illness in the first stages, yet here a miner was compelled to carry on until he was totally incapacitated. He appealed to the Home Secretary to drop out the word "acute."

Mr. HILTON said he had considerable experience of mills in Lancashire, and most of the accidents he had come across had been due to carelessness. The more fencing put round the machinery the more likelihood of accidents—speaking more especially of fast-revolving machinery where the chief accidents were from burning and friction. It had been suggested—surely not seriously—that every big mill should have a medical staff. In every large town in England they had a most up-to-date medical staff in the local infirmary on the spot to which cases could be taken and treated with scientific knowledge. They provided first-aid in every mill, and a medical man attached to every mill would be unwarrantable.

Mr. ROBINSON said that there was a committee sitting with regard to accidents and also a committee inquiring into dust and fibre. What were those committees doing? The injury from accidents was nothing compared with that from dust, where the life was taken away from a man between 30 and 40.

Dr. VERNON DAVIES said that in regard to factory regulation they had to depend largely on the honesty and goodwill of employers and their desire to do their best for their workpeople, as well as to obey the law. There were many who regarded it as a retrograde step when the inspection of accidents was taken away from the certifying surgeons. That was done by decree of the Privy Council to save £7000 per annum. Formerly accidents were reported to the certifying surgeon, who had to proceed to the mill and see the actual machine, decide between the negligence of the employer and the carelessness of the worker, and make suggestions on the spot. Now a report, possibly inaccurate, was made to the inspector, who decided whether to visit the place or not. The certifying surgeon had to go to the office and certify and never need go into the works. He would like to ask the Home Secretary what his present opinion of the certifying surgeon was. The Secretary for Mines (Colonel Lane Fox) had obtained the impression that possibly certain alterations would be carried out. That was the gist of an answer given in the House. Dr. Davies would like the Home Secretary to inquire through the department into the work of the certifying surgeon in the last few years and to compare it with the work they did formerly, and see whether one of the most efficient State services, and also one of the cheapest, was not the certifying surgeon. Any alteration in the status of the certifying surgeon was probably a retrograde step. He was at present a trained medical man with a very good knowledge of industrial processes. Every accident was reported to him, he was frequently in the mill and constantly on the look-out for errors, and he could be of the greatest use to the Home Secretary and his department. Accidents were not always the fault of the staff, or even the fault of the workmen; they were sometimes the fault of the guard that was put on the machine. The medical man was of use at a time like that. The medical man's knowledge in coöperation with the factory inspector could be a very great help. He would be glad if the Home Secretary would pay particular attention to the possibility of securing coöperation between the work of the surgeon and the factory inspector and of entrusting the inspection of accidents again to the certifying surgeon.

Mr. PALING urged that silicosis should be scheduled in connexion with the mining industry so that men suffering from this disease could obtain compensation. He said that in the opinion of doctors who had to deal with these cases coal-miners were just as liable to contract the disease as men who worked, say, in a silica mine. He also asked, in view of the alarming increase of nystagmus, that something further should be done.

Sir W. JOYNSON-HICKS said that obviously if the Home Office had more factory inspectors there would be more inspections made, but he had to balance the claims of the Treasury with the claims of perfection in administration. He was bound to ask—and they were responding gallantly to the appeal—the departmental staff of factory inspectors to work harder and harder in order to cope with the increased work without having to apply to the Treasury for an increase in the number of inspectors. When they had got through their difficulties, and when perhaps the Factory Bill of next year had passed into law, that would be the time to approach the Treasury. In accordance with the report of the Departmental Committee on Industrial Diseases no disease was scheduled by the Home Office unless it complied with certain conditions. First of all it must be a disease and not an accident within the meaning of the Act. Secondly, it must be a disease such as would disable the workman for the minimum period, not less than four days, necessary for compensation. Thirdly, it must be a disease specific to the employment, so that its causation by the employment could be determined in individual cases. He had been in consultation with the Ministry of Health, and they had agreed to institute a special investigation into cattle ringworm disease with a view to determining how far it could properly be included in the list of industrial diseases. He hoped the investigation would be completed very shortly, and then the matter would come up for final decision. Miners' nystagmus had always been scheduled. In 1908 there were 386 new cases and 74 old cases. In 1925 there were 3445 new cases and 7890 old cases. The effect was to reduce the output of the industry in which the disease occurred. After very full investigation a committee of the Medical Research Council made in 1923 a number of recommendations for improving the position. The Home Office at once drew up a scheme to give effect to those recommendations, and it was not the fault of the department that the matter had not been pressed forward. The Mining Association had furnished him with their views on the scheme, but the Miners' Federation had not yet done so. If the views of that organisation were such as commended themselves to him he hoped to have a better scheme before long for dealing with this terrible disease. As regarded bursitis, the point he had to consider was how far bursitis without inflammation was incapacitating. The Medical Research Council had dealt with the point and said:—

> "A chronic enlargement of the bursa in front of the knee or elbow should not be certified as an industrial disease unless the chronic condition becomes acutely inflamed as the result of work. Chronic enlargement of these bursæ does not cause any incapacity. The certifying surgeon must always satisfy himself that the condition is an acute inflammation arising out of the workmen's employment and of sufficient severity to cause loss of earning power."

If any medical evidence could be produced to prove that there was a bursitis which was not associated with acute inflammation, but which nevertheless disabled the worker, he was quite prepared to reconsider the position.

Dr. DAVIES: A man might have bursitis causing a certain kind of pain which would not come under the definition.

Sir W. JOYNSON-HICKS: It is no doubt very difficult for the layman to define. I did not read the whole of the report of the Medical Research Council. There is a further clause which may deal with the point raised by my hon. friend:—

> "The certifying surgeon must always satisfy himself that the condition is an acute inflammation arising out of the workman's employment and of sufficient severity to cause loss of earning power."

That is the position which I have been bound to take up, and unless hon. Members can produce medical evidence that bursitis in itself can cause not merely pain, but loss of earning power without it becoming acute, and even before it becomes acute or inflammatory, I must be bound by the medical report placed before me. Continuing, the right hon. gentleman said that the last disease with which he would deal was silicosis. That disease had not been scheduled, but he could provide compensation for it under special powers conferred by the Workmen's Compensation and Silicosis Acts. Inquiries were proceeding that might lead to the formulation of a scheme.

The vote was agreed to.

DISEASES OF ANIMALS BILL.

ON Friday, July 15th, on the motion for the third reading of the Diseases of Animals Bill,

Mr. A. V. ALEXANDER said that it was argued by the Minister of Agriculture that the Bill would help to get rid of tuberculosis in the herds of the country. While it would not be detrimental from that point of view, it would not secure anything like the amount of advantage either to the herds or to the health of the people that was desirable. The percentage of tuberculosis to be found in the herds of the country was stated to be of very varying degree according to where the statement came from. Some people said that it was as high as 70 per cent. in milch cows of from 10 to 15 years old; others said it was 30 per cent. to 40 per cent., taking dairy cattle as a whole. But they had plenty of evidence from milk tests to show that there was very real danger to the people of the country from the failure to arrest in any great degree the existence of tuberculosis in our herds. Dr. Nathan Raw had said: "It is a sad reflection on our milk-supply to know that over 15 per cent. of all milk supplied to the public contains living tubercle germs which have the power to produce disease in children and young adults."

Brigadier-General BROWN said that one reason why he welcomed the Bill was that he thought Canadian heifers coming into this country would be much more liable to get disease, especially tuberculosis, than our own heifers.

Mr. GUINNESS (Minister of Agriculture) reprobated propaganda against our own dairy cattle at a time when British agriculture was in great difficulty. It was cruel to condemn a very wholesome food and a very valuable agricultural product upon misleading evidence. The hon. Member quoted Dr. Nathan Raw as an authority for the statement that 15 per cent. of the milk in this country was tuberculous. They had got some figures as the result of 18 months' working of the Tuberculosis Order. Between Sept. 1st, 1925, and March 31st, 1927, owing to the notification of tuberculosis on dairy farmers' premises, and owing to evidence got from the other end by tuberculous milk being traced back, inspections were made of premises, including 1,051,000 cattle, a seventh or eighth of the total head of cattle in the country. Among those cattle there were 792,000 cows and heifers, and of those there were 21,871 which were found to be suffering from those forms of tuberculosis which brought them within the Order—not 15 per cent., but 2·7 per cent. No doubt the one-half of 1 per cent. which was the figure he had quoted could easily be brought up to 15 per cent. in respect of milk sold over the counter in certain unfortunate dairies. He thought that was the explanation of the terrifying but quite unfounded figure given by Mr. Alexander.

The Bill was read a third time and passed.

HOUSE OF LORDS.

MONDAY, JULY 18TH.

Midwives and Maternity Homes (Scotland) Bill.

THE Midwives and Maternity Homes (Scotland) Bill (which has already passed through the House of Commons) was read a second time.

Medical and Dentists Acts Amendment Bill.

The Medical and Dentists Acts Amendment Bill, a measure which is to confirm and give effect to certain agreements between representatives of Great Britain, the Irish Free State, and Northern Ireland as to the registration and control of medical practitioners and dentists, and to validate certain acts done by the Dental Board, was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 13TH.

Slum Clearance Schemes.

Mr. BUXTON asked the Minister of Health whether, in view of his recent statement that progress would shortly be made with the improvement of slum conditions, he would state what steps he proposed to take.—Major COPE replied: Ninety-eight schemes for the clearance of slum areas in various parts of the country have so far been confirmed, and my right hon. friend anticipates that in view of the progress which is being made generally with house building, local authorities will shortly be able to turn their attention in a greater degree to this aspect of the housing problem. As the right hon. Member is no doubt aware, local authorities already have very wide powers, and provision is made in the Housing Act of 1923 for the grant of Exchequer.

MONDAY, JULY 18TH.

Milk Consumption in Great Britain.

Major GLYN asked the Minister of Agriculture what was the estimated daily consumption of fresh and tinned milk in Great Britain, respectively; what proportion of the fresh milk was distributed by the large dairy companies; how much through the agency of coöperative retail societies; and what proportion of the daily supply was either Grade A or Certified.—Mr. GUINNESS replied: Until the results of the Scottish Agricultural Census and of the Industrial Census of Production for Dairy Produce are available, any figures as to the consumption of fresh milk in this country can only be very approximate. It is estimated, however, that the average daily consumption of fresh milk in Great Britain is probably between 2¼ and 2½ million gallons, and of imported tinned milk (used as liquid milk and for other purposes) about 6500 cwt., or the equivalent of 210,000 gallons of liquid milk. With regard to the second and third parts of the question, I understand that in the larger towns and cities from 12 to 15 individual firms, including retail coöperative societies, handle, as a rule, the bulk of the milk-supplies, but I have no precise information for the country as a whole as to the proportion handled by what my hon. and gallant friend calls "the large dairy companies" or by the "coöperative retail societies." It is estimated that "Certified" and "Grade A" milk (including tuberculin-tested milk) account for about 1 per cent. of the fresh milk consumed.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregation held on July 14th the following degrees were conferred:—

M.Chir.—R. S. Corbett.

M.B. & B.Chir.—G. L. Alexander, G. M. Tanner, H. F. Griffiths, H. P. Nelson, and E. S. Page.

B.Chir.—H. S. Allen, C. F. Watts, H. M. Elliott, V. C. J. Harris, C. E. Kellett, D. N. R. Jones, and R. Watson.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council held on July 14th Sir Berkeley Moynihan was re-elected President, and Sir Cuthbert Wallace and Mr. F. J. Steward were re-elected Vice-Presidents for the ensuing year. Sir Cuthbert Wallace and Mr. Hugh Lett, the recently elected members of Council, were introduced and took their seats in the Council. In consequence of the redecoration of part of the museum it was decided to close it during August as well as September and, if necessary, for part of the present month. A vote of thanks was given to Lady Bland-Sutton for presenting to the College a portrait by the Hon. John Collier of Sir John Bland-Sutton, past-President of the College.

The following professors and lecturers were elected for the ensuing year:—

Hunterian Professors.—Sir Arthur Keith, Mr. Percy Sargent, Mr. G. Grey Turner, Mr. H. S. Souttar, Mr. W. E. M. Wardill, Mr. E. Miles Atkinson, and Mr. J. H. Sheldon.

Arris and Gale Lecturers.—Mr. A. Abrahams, Mr. A. Fleming, Miss Ida C. Mann.

Erasmus Wilson Lecturers.—Mr. W. D. Newcomb, Mr. C. F. Shattock, Mr. C. P. G. Wakeley.

Arnott Demonstrator.—Sir Arthur Keith.

The diploma of Fellow was conferred upon Richard A. Brews, London Hospital, and the diploma of Member was conferred upon Phyllis M. Robottom, Westminster Hospital.

The under-mentioned diplomas were conferred upon the following candidates, jointly with the Royal College of Physicians:—

Diploma in Laryngology and Otology.—M. O. Abdeen, J. L. Baird, J. Bernstein, C. H. C. Byrne, E. E. Day, E. W. Gutteridge, D. R. Macgregor, R. M. Savage, W. M. Snodgrass, G. E. Tremble, Mary A. Wiles, and W. C. Wood.

Diploma in Psychological Medicine.—S. M. Coleman, G. L. Graham, F. H. Healey, S. Hillier, E. G. Howe, W. McCartan, Doris M. Odlum, T. Paton, F. E. E. Schneider, F. L. Scott, G. N. O. Slater, and T. Tennant.

Licences in dental surgery were conferred upon the following candidates who have passed the requisite examinations and have complied with the by-laws:—

H. J. Askew, Royal Dental; R. A. Bagg, V. H. D. Bascomb, E. Britstone, and N. B. Coltart, Guy's; R. R. Dalby, Manchester; R. L. Dale and E. J. Dalling, Guy's; A. Deverall, C. T. Dodd, and S. W. Felce, Royal Dental; S. C. Gilby, Birmingham; H. A. Ginn and E. M. Greenwood, Guy's; H. L. Hill, Royal Dental; F. S. Hobbs, Guy's; A. Jackson, Royal Dental; N. A. James, Univ. Coll.; E. N. F. Jenkins, Royal Dental; H. H. Kenshole, Guy's; Margaret C. Lauder, Royal Dental; L. L. Lester and W. V. Levy, Guy's; J. Luke, Royal Dental; K. Malik, London; A. G. Mockridge, Royal Dental; M. J. O'Donnell and C. O'Donoghue, Guy's; H. Peake, Manchester; W. J. Preston, Royal Dental; R. F. Prichard and J. R. Prior, Guy's; K. P. Ramsay, Pennsylvania and Royal Dental; E. B. Redman; R. S. T. Sandberg, J. H. Sedgman, and A. F. L. Shapland, Royal Dental; S. Sharp, Guy's; J. N. Stato, Royal Dental; K. D. Sutcliffe, Leeds; E. J. Taylor, Royal Dental; D. A. Thomas, Guy's; A. Topping, Liverpool; R. T. Towne and P. R. Walter, Guy's; and J. R. William and R. C. Withers, London.

UNIVERSITY OF BELFAST.—At a graduation ceremony on July 8th the following honorary degrees were conferred :—

LL.D.—Sir Almroth Wright.

D.Sc.—Sir Berkeley Moynihan and Prof. Elliot Smith.

UNIVERSITY OF BIRMINGHAM.—At recent examinations the following candidates were successful :—

FINAL EXAMINATION FOR M.B., CH.B.

W. B. Ballenden, St. Clair H. Baynes, E. L. Butler, H. E. Carmalt, A. S. Esslemont, K. P. Fooks, Helen G. Gifford, F. E. Hampton, S. Hobson, R. L. Jones, Marjorie V. Martin (Distinction in Medicine), Marjorie H. Mills, Margaret Mitchell, Phyllis M. Paddock, Mary E. Percy, S. H. Reeves, A. H. Richardson, V. H. Sarland, Ahmad Sirry, Frances M. Stockdale, Olive F. Sydenham, A. D. Tomlins, and F. Welsh.

FINAL EXAMINATION DIPLOMA IN DENTAL SURGERY.

Old Regulations.—C. T. Morgan and A. H. Bosworth.

Revised Regulations.—S. L. Barnacle, W. H. Brown, W. L. Eccleston, Bertha H. Johnson, R. E. Morgan, Gerald Simons, and A. T. Wynne.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial held on July 14th the following degrees were conferred :—

M.D.—‡ Harriette G. Bogle, ‡ Gladys H. Dodds, * John Gray, F. S. Harper, * R. G. Inkster, † G. M. Lamb, * C. G. Lambie, F. W. Lang, † O. J. S. Macdonald, Ella G. F. MacKenzie, Rosanna E. Macmillan, ‡ A. J. Muirhead, ‡ J. R. K. Paterson, ‡ Elsie Porter, G. W. Simpson, and J. A. B. Young.

* Awarded gold medal for thesis.
† Highly commended for thesis.
‡ Commended for thesis.

Ph.D.—G. H. Percival.

M.B., Ch.B.—J. P. S. Bannerman, Norman Baxter, R. L. Beveridge, W. K. Blackie, § J. D. Bottomley, Julius Brown, T. G. Brown, J. A. Bruce, W. N. Campbell, L. G. Carmichael, D. C. Chopra, W. F. H. Coulthard, E. C. Davies, J. B. Dedman, A. W. Dunn, G. H. Duthie, A. C. Edwards, J. C. S. Edwards, Hannah M. M. Elder, Gilmour Erskine, I. B. Ewart, I. J. Freedman, Mavis E. Furst, G. W. Gale, C. O. Gange, H. P. S. Gillette, A. L. Goldberg, E. W. Graham, S. H. Graham, H. B. Gray, G. A. H. Gumley, O. K. G. Guyer, A. P. Harris, R. M. Hill, Dorothy Hunter, § J. R. Innes, W. M. Innes, § A. S. Johnstone, H. D. G. Jones, Bhagwan Das Khurana, A. L. Knipe, S. Kramer, D. G. L. Lackie, A. A. Learmont, G. A. Lee, M. E. Lemin, Mary L. Liston, Isabella M. B. Livingstone, J. W. Lusk, K. S. Macdonald-Smith, I. Bruce-Kerr MacGregor, R. M. M'Gregor, R. S. MacHardy, D. W. D. MacLaren, § Wilhelmina M. G. MacLennan, I. M. Macleod, § J. M'Michael, § A. A. MacNair, D. R. Maitland, R. S. Manson, Edith M. Martin, T. R. Matson, H. Mercer-Rickets, Brian de la Harpe Meyer, T. C. Mitchell, W. J. Mowat, C. E. Munro, Pauline V. Murray, Diwan Pitamber Nath, H. J. Nicholson, N. J. Nicholson J. H. Nicolson W. J. Officer, Beatrice M'P. Ogilvie, Katharine M. Ogilvie-Mullan, J. D. W. Pearce, W. R. Playfair, G. L. Reid, Hannah M. Reid, § T. M. Reid, § W. A. Robb, J. E. Robson, B. Rogoff, A. W. Rose, Jessie I. Rosie, W. A. R. Ross, R. Sampson, P. N. Seager, H. M. Shenkin, Aga Mohamed Hadi Shirazi, Frances E. Smith, Georgina M. Somerville, Kok Ho Teik, D. Tennant, T. P. Thomas, Margaret Venters, E. A. Watson, J. Weinstein, L. Whitten, B. Williams, C. H. Wilson, Marion R. Wilson, G. M. M. Wright, Cecilia E. L. Wyllie, G. M. Yates, A. L. Young, J. H. Young.

§ Passed with honours.

Diploma in Tropical Medicine and Hygiene.—Syed Abdur Rahman.

Diploma in Radiology.—Ruth M. C. Barclay, T. Brewis, B. T. Halliwell, and J. B. King.

The Cameron Prize in Practical Therapeutics was awarded to Dr. F. G. Banting, Professor of Medical Research in the University of Toronto, for his contributions to physiology and medicine, relating to insulin. Other prizes and distinctions were awarded as follows :—Straits Settlements Gold Medal : Dr. G. Buchanan. Ellis Prize in Physiology : M. H. Finkelstein. Gunning Victoria Jubilee Prize in Anatomy : Dr. D. Mainland. Gunning Victoria Jubilee Prize in Medicine : Dr. R. V. Christie. Lauder Brunton Prize in Pharmacology and Therapeutics : Dr. G. H. Percival. Ettles Scholarship and Leslie Gold Medal : Dr. J. M'Michael. Allan Fellowship in Clinical Medicine and Clinical Surgery : Dr. J. M'Michael. The Murchison Memorial Scholarship in Clinical Medicine : Dr. J. M'Michael. M'Cosh Graduate's and Medical Bursaries : Dr. W. A. Robb. The Mouat Scholarship in the Practice of Physic : Dr. J. D. Bottomley. Buchanan Scholarship in Gynæcology : Dr. D. G. L. Lackie. James Scott Scholarship in Midwifery : Dr. Wilhelmina M. G. MacLennan. Beaney Prize in Anatomy and Surgery : Dr. J. D. Bottomley. Conan Doyle Prize : Dr. G. W. Gale. Annandale Gold Medal in Clinical Surgery : Dr. T. M. Reid. Murdoch Brown Silver Medal in Clinical Medicine : Dr. J. M'Michael. Royal Victoria Hospital Tuberculosis Trust Gold Medal : K. S. Macdonald-Smith. Scottish Association for Medical Education of Women Prize : Dr. W. M. G. MacLennan. Dorothy Gilfillan Memorial Prize : Dr. W. M. G. MacLennan. Pattison Prize in Clinical Surgery : Dr. John M'Michael. Prox. acc., Dr. W. K. Blackie. Wightman Prize in Clinical Medicine : I. Aird. Wellcome Medals and Prizes in the History of Medicine : Gold Medal, Dr. J. D. A. Gray; Silver Medal, Dr. G. W. Gale. Cunningham Memorial Medal and Prize in Anatomy : A. C. P. Campbell. Whiteside Bruce Bursary : Thomas H. Brown.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At recent examinations the following candidates passed the Final Examination for the Diploma of L.D.S. :—

Donald Wilcock, John Stobo-Nancer, Alfred William Hendry, Stanley Leonard Cramer, Betty Cossar Hamilton, Charles Alexander Johnston, Alexander Stuart Roberts, Thomas David Hume Millar, Robert Wilson, James Rankin Wishart, David Dunnet, and Barryhill Moore.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH. A quarterly meeting of the College was held on July 12th, the President, Prof. G. M. Robertson, in the chair. Dr. Alfred Irving Shepheard-Walwyn (Carlisle) and Dr. Walter Duncanson Chambers (Perth) were introduced and took their seats as Fellows of the College. Dr. Robert Victor Morrison (Rangoon), Dr. William Macrae Taylor (Edinburgh), Dr. Douglas James Ackworth Kerr (Edinburgh), Dr. William Alister Alexander (Edinburgh), and Dr. Thomas Robert Rushton Todd (Edinburgh) were elected Fellows.

HOUSING AND TOWN-PLANNING.—The Garden Cities and Town-Planning Association is arranging a tour to Newcastle, Edinburgh, Glasgow, and Carlisle from Sept. 16th to 23rd. Particulars may be had from the Secretary, 3, Gray's Inn-place, London, W.C. 1.

MARIE CELESTE ANNEXE FOR MEN.—Last week Mr. Neville Chamberlain (Minister of Health) opened the Marie Celeste annexe at Reigate for men patients of the London Hospital. Formerly a large private house, the annexe is intended to accommodate 20 patients nearing the convalescent stage. Mr. Chamberlain said that the great advantage of annexe treatment was, taking hospital services as a whole, that it enabled a far greater use to be made of all the available services, so that better value was obtained for their money. The idea of annexes was of national importance. These 20 beds would perhaps mean the saving of thousands of lives in the future, as they would prevent people from having to wait for a bed at the London Hospital until it was too late.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Tuesday, July 26th, at 5 P.M., Mr. A. Caddy will give a lecture-demonstration on Glaucoma at the Royal Westminster Ophthalmic Hospital. This lecture-demonstration is free to all members of the medical profession. Two special courses have been arranged by the Fellowship for August—viz., a course in Diseases of Infants at the Infants Hospital under the direction of Dr. Eric Pritchard, from August 8th to 21st, from 2 P.M., daily, and a course in Medicine, Surgery, and the Specialties from August 29th to Sept. 10th at the Queen Mary's Hospital, Stratford, which will occupy almost the whole day. This hospital has a good pathological department and excellent maternity wards. Apart from these special courses, the Fellowship provides a general course of instruction at the associated hospitals. A comprehensive ticket is issued for any period from one week to one year and the holder is free to make up his own time-table. Copies of all syllabuses are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, W. 1, from whom the *Post-Graduate Medical Journal* may be had at 6*s.* per annum post free.

MEDICAL INSURANCE AGENCY.—The Chairman's report for the year 1926, presented at a recent meeting of the Agency, showed a steady progress. The year was a record one in life assurances. The Agency received in 1926, on behalf of various recommended companies, 237 proposals to secure sums assured of over £200,000. Of these 202 (£172,916) proposals were completed in the year, whilst 23 (£23,700) were declined, deferred, or were not taken up by the proposers, and 12 (£12,263) were transferred to 1927. Apart from ordinary life and endowment assurances, the Agency has arranged many contracts for the benefit of children for educational purposes and for protection in later life. The doctors' special policy for the insurance of motor-cars also showed a considerable increase in the number of new contracts negotiated. The demand for the services of the consulting engineers continues to grow, and more frequent use is being made of their services in connexion with the purchase, hire, and repair of cars and also as arbitrators. The scheme whereby medical practitioners may obtain financial assistance in the purchase of partnerships or practices is now nearing the end of the experimental period, and with the cordial coöperation of insurance experts will soon be a recognised form of business. Grants to the amount of £1911 5*s.* were made to medical charities during 1926, the total distributions to the end of that year being £16,306, divided as follows : Royal Medical Benevolent Fund, £4749 ; Royal Medical Benevolent Fund Guild, £4673 ; Epsom College, £3628 ; educational grants (girls), £1147 ; sundry charities, £2108. The committee of management resolved to make the following further distributions : R.M.B.F. and R.M.B.F. Guild, to each £525 ; Epsom College Benevolent Fund, £210 ; B.M.A. Charities Fund, £125.

DUNDEE HOSPITAL.—Dundee Royal Infirmary has received a gift of £28,000 towards the endowment of a maternity hospital.

ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND.—This association invites applications for a surgical scholarship of the value of £350 for one year. Particulars will be found in our advertisement columns.

PRESENTATION TO A MEDICAL MAN.—Dr. G. J. B. Candler-Hope, chairman of the North Riding Panel Committee since 1913, has been presented with a cheque for £100 and a gold cigarette case by the medical practitioners of the North Riding of Yorkshire.

Dr. R. King Brown, medical officer of health for Bermondsey, has been appointed medical editor of the *British Journal of Actinotherapy*. Dr. Brown is chairman of the Executive Committee of the Institute of Hygiene.

PLAGUE-INFECTED RATS.—It is stated that two grain ships recently arrived in London from the Argentine have been found to harbour rats infected with plague. Appropriate measures have been taken by the port sanitary authorities.

LEGACY FOR MEDICAL RESEARCH.—Mr. William Henry Travis, of Christchurch, New Zealand, has left the whole of his estate, valued at about £40,000, for the assistance of individuals capable of scientifically investigating the causes and cure of cancer and consumption.

IN an annotation appearing in THE LANCET of July 9th and noting the attendance of the medical profession at the 1300th anniversary of the consecration of York Minster, we omitted to mention that the Royal College of Physicians of London was represented at the function by Dr. A. G. Barrs.

KING FUAD AT ROYAL FREE HOSPITAL.—King Fuad visited the Royal Free Hospital during his recent visit to England and presented £400 for the endowment of a bed, which will bear his name. Six Egyptian women are studying medicine at the hospital with the object of developing maternity and child welfare work in their own country.

GIFTS FOR PLAYING FIELDS.—The National Playing Fields Association has announced a gift of £10,000 from the trustees of the London Parochial Charities. It will be payable in amounts of £2000 spread over five years, and is specially allocated to the London and greater London area. A cheque for £10,000 has been sent by the London Stock Fund.

MEMORIAL TO DR. STEWART HUTCHINSON.—The organisers of the memorial to the late Dr. Stewart Hutchinson of Hove have given £105 to the Royal Alexandra Hospital for Sick Children, Dyke-road, Brighton, to endow a cot during the lifetime of Mrs. Hutchinson. The balance of the fund—£41 8*s*. 6*d*.—has been forwarded to the same institution for the operating theatre fund in the hope that a tablet may be placed in the theatre.

THE LATE DR. A. BRUCE LOW.—Dr. Alexander Bruce Low, who recently died at Norwood, was born at Edinburgh in 1856, and was educated at the universities of Edinburgh and Vienna. He graduated in medicine in 1878, proceeding to the M.D. degree in 1881; three years later he became a Member of the Royal College of Physicians of Edinburgh, and in 1897 he was elected a Fellow. Soon after qualifying he was appointed house surgeon to the Sunderland Royal Infirmary, and from 1886 to 1914 was honorary physician to this institution, becoming consulting physician in 1918. He also joined the honorary staff of other hospitals in the neighbourhood. Dr. Low spent the last few years of his life in Finchley and Norwood, and his son, Dr. Herbert Bruce Low, took over the practice at Sunderland.

SCROTAL CANCER.—"Death from epithelioma caused through contact with tar" was the finding of a Manchester jury at an inquest on June 29th. The deceased had worked at the corporation gasworks for about 25 years and had had three operations for his disease. The coroner, Mr. C. W. W. Surridge, stated that it was a pity that men who were subject to cancer on the scrotum did not voluntarily submit themselves to periodical examination. Taken in time the disease was curable. Dr. S. A. Henry informed the coroner of one firm whose employees submitted themselves at varying intervals to medical examination at the firm's expense. Mr. Ryecroft said that the manager at the Manchester Corporation gasworks had given lectures to the workmen and warned them of the danger of going to the lavatory without first washing their hands. Unfortunately the men strongly resented the idea of medical examination, and until the legislature stepped in he was afraid that little progress would be made.

ENLARGEMENT OF SAVERNAKE HOSPITAL.—The opening of the extension to Savernake Hospital was performed recently by the Marchioness of Ailesbury. The main buildings are due south of the older portions of the hospital, and consist of two wings and a single open corridor. An unusual feature is the use of shop blinds along the south side of each wing, so that patients can be wheeled direct into the air from the wards under cover. A roof garden is provided on each wing.

CIVIL LIST PENSIONS.—The list of pensions granted under the Civil List Act (1910) in the year ended March 31st, 1927, has just been issued and contains the following names: Mrs. Colette Anne Marguerite Inman, in recognition of the contributions made by her husband, Arthur Conyers Inman, M.B., to the pathology of tuberculosis, £75. Dr. George Alexander Pirie, in recognition of his self-sacrificing and devoted services to the application of radiology to medicine, £75. Mr. George Chisholm Waldemar Williams, F.R.C.S., in recognition of his self-sacrificing and devoted services in the routine application of Rontgen rays to the treatment of disease, £50.

THE LATE DR. C. K. SCALES.—At the age of 32, Dr. Cedric Kennedy Scales died at Margate on July 6th. The son of a Dorking solicitor, he was educated at Epsom College and King's College Hospital. On the outbreak of war, whilst still a student, he entered the Navy as surgeon-probationer, and after taking the degree of M.B. Lond. in 1918 he left the service with the rank of surgeon-lieutenant. Following house appointments at King's College Hospital he settled in practice at Margate in partnership with Dr. J. J. Suckling, whose sister-in-law he married. A year or two ago, after a period of further hospital study, he took up a practice in Putney, but since last January illness had prevented him from continuing the work save for short periods.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, July 25th.—9 P.M., COMBINED MEETING OF THE SECTION OF NEUROLOGY WITH THE AMERICAN NEUROLOGICAL ASSOCIATION. Reception by Sir James Berry (President of the Society) and Lady Berry. At 9.30 P.M. a lecture will be delivered by Sir James Purves-Stewart (President of the Section of Neurology) on Mount Athos, a Survival of the Middle Ages. Fellows of the Society are cordially invited to be present at this reception.

TUESDAY.—9.30 A.M., Short Papers. 2 P.M., Short Papers.

WEDNESDAY.—9.30 A.M., Discussion on The Cerebellum. To be introduced by Dr. F. Tilney, Dr. H. A. Riley, Dr. L. J. Pollock, Dr. L. E. Davis, Dr. A. J. Musser, Dr. T. H. Weisenburg, and Prof. Harvey Cushing. 2.30 P.M., Clinical Meeting.

THURSDAY.—9.30 A.M., Discussion on Sensory Disorders in Organic Disease of the Nervous System. To be introduced by Prof. J. S. B. Stopford, Dr. Wilfred Harris, Dr. Gordon Holmes, and Dr. S. A. Kinnier Wilson. 2 P.M., Short papers and demonstrations of pathological subjects. 5 P.M., Hughlings Jackson Lecture by Dr. Charles L. Dana. 8 P.M., Banquet (for Members of the Section and their guests).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE and POST-GRUADUAT MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, July 25th to SATURDAY, July 30th.—FELLOWSHIP OF MEDICINE LECTURE-DEMONSTRATION. Tues., 5 P.M., Mr. A. Caddy on Glaucoma at the Royal Westminster Ophthalmic Hospital, Charing Cross, W.C. Open to all members of the medical profession without fee. WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Lecture-demonstrations, daily at 5 P.M. Last week of course.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 25th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M. Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinic. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 25th.—10 A.M., Mr. Macdonald: Genito-Urinary Operations. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Addison: Operations. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10.30 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.
FRIDAY.—10 A.M., Sir Henry Simson: Gynæcological Operations. 10.30 A.M., Dr. Downing: Skin Dept. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.
Operations, Medical and Surgical Out-patients, Special Departments, daily, 10 A.M. to 5 P.M. Saturdays, 10 A.M. to 1 P.M.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, July 26th.—3.15 P.M., Mr. G. G. Penman: Iritis.

Appointments.

BOOTH, W. G., M.B., B.S. Lond., D.P.H., has been appointed Assistant Medical Officer of Health, Finsbury.
CLAUSEN, R. J., M.B., B.S. Lond., Anæsthetist, Charing Cross Hospital.
WILKINSON K. DOUGLAS, O.B.E., M.D. Birm., M.R.C.P. Lond., Cardiologist to the Birmingham City Fever Hospitals.

Vacancies.

For further information refer to the advertisement columns.
Alton, Hants, Lord Mayor Treloar Cripples' Hospital.—Asst. Res. M.O.
Association of Surgeons of Great Britain and Ireland, 51, Wimpole-street, W.—Surgical Scholarship. £350.
Beckenham Urban District Council.—M.O.H. and School M.O. £900.
Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.
Bristol Royal Hospital for Sick Children and Women.—H.S. £125.
Charing Cross Hospital, W.C.—Res. M.O. £400.
Colchester, Essex County Hospital.—H.S. £150–£200.
Doncaster Royal Infirmary and Dispensary.—Third H.S. At rate of £150.
Irish Government.—Dist. M.O. £500.
Hertford County Hospital.—H.S. At rate of £150.
Hull Royal Infirmary.—Cas. H.S. At rate of £150.
Liverpool, Smithdown-road Institution.—Res. Asst. M.O. £200.
Manchester, Ancoats Hospital.—Res. Surg. O. £200.
Northamptonshire County Council.—Tuberculosis O. £750.
Plymouth, Homœopathic and General Hospital.—H.S. At rate of £100.
Rochford Union.—Dist. M.O. and Public Vaccinator. £170.
St. Leonards-on-Sea, The Buchanan Hospital.—H.S. £150.
St. Mary's Hospital for Women and Children, Plaistow.—Res. M.O. and Asst. Res. M.O. £175 and £130.
St. Pancras Parish, Dists. 5, 6, and 7.—Public Vaccinator.
Samaritan Free Hospital for Women.—H.S. At rate of £100.
Scottish Board of Health.—Dist. M.O. £1000.
Sheffield Royal Hospital.—Res. Surg. O. £200.
Southampton Parish Infirmary.—Third Asst. Res. M.O. £275.
Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £200.
Staffordshire County Council, County Laboratory, Lichfield.—Bacteriologist (Locum Tenens). £10 10*s.* weekly.
Swansea Hospital.—H.S. £150.
Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £300.
Worcester General Infirmary.—Sen. and Jun. Res. M.O.'s. £180 and £120 respectively.
The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Roade (Northampton), Okehampton (Devon), Ludlow (Salop), Tunbridge Wells, (Kent), Liverpool (Garston), and Lancaster, Kilbirnie (Ayr).

Births, Marriages, and Deaths.

BIRTHS.

CHANDLER.—On July 13th, 1927, at 1, Park-square West, Portland-place, W.1, to Marjorie, wife of F. G. Chandler, M.D., F.R.C.P.—a daughter.
GLEN.—On July 8th, at Acton, W., the wife of Archibald Glen, L.R.C.P., M.R.C.S., of a daughter.
HOLDEN.—On July 17th, 1927, at Byron House, Aylesbury, Jean, the wife of Sandys J. C. Holden, M.B., D.P.H., of a daughter.

MARRIAGES.

DOWNING—PEGG.—On July 12th, at St. Peter's, Oadby, Frederick John Downing, L.D.S. R.C.S. Eng., to Violet Constance, daughter of Mr. and Mrs. S. H. Pegg, of Leicester.

DEATHS.

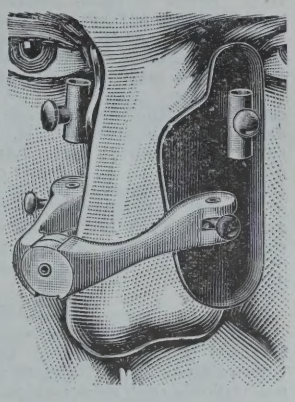
LOW.—On July 12th, suddenly, at Kewferry-road, Northwood, Middlesex, Alexander Bruce Low, M.D., F.R.C.P. Edin., aged 70.
MACKAY.—On July 14th, at Heathmount, Tain, William Alexander Mackay, M.D., F.R.C.S. Edin., of Huelva, Spain.
NIXON.—On July 15th, 1927, after an operation, Horace Clulow Nixon, M.D., of Queen's-parade, Bath.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

DIATHERMY FOR THE COMMON COLD.

IN *Paris Médical* for June 11th Dr. H. Bordier, of Lyons, describes a method of treating acute coryza by diathermy. The proposal was first made, he says, by Dr. Tsinoukas, of Athens, and the treatment aims at producing heat in the nasal fossæ sufficient to stop the excessive secretion of the mucous glands. Dr. Tsinoukas made use of two large Hegar's dilators (No. 26), applying them to the skin on each side of the nose. He claimed that even with a small current (200–300 milliampères) the most acute coryza could be stopped almost at once, so that after about 25 minutes the patient was cured; he could breathe freely, he ceased to sneeze, there was no discharge from the nose, and little by little any pain in the frontal sinuses disappeared. The best results were obtained if diathermy was used at the very beginning of the cold.



Dr. Bordier records the same success, but sought to devise more convenient apparatus. For the Hegar's dilators he first substituted spoon-shaped electrodes fixed to insulating handles; the patient comfortably seated in an armchair, held these handles for himself and applied them to the nasofacial angle. He now uses a nasal bipolar electrode (made by Mr. Lépine, place des Terreaux, Lyon), an illustration of which we reproduce by courtesy of the publishers of *Paris Médical*, Messrs. J. B. Baillière et Fils, Paris. It consists of two metal plates, 1 mm. in thickness, fixed to the arms of a V made of an insulating substance, a joint at the base permitting adjustment of the plates to any nose. A terminal on each plate receives the electric wire, which should be supple and light. Lastly, an elastic band round the head immobilises the apparatus once it is in place. The advantage of Dr. Bordier's model is that it can be used without the patient's active help. The amount of current is increased until the patient remarks a sharp sensation of heat within the nose. It is to be noted, Dr. Bordier says, that if the coryza is confined to one side of the nose, that is the side on which most heat will be felt, a fact which is explained by the higher tension of the current in the region of the diseased mucosa, following more abundant secretion from it. As the application continues with this amount of current, the sensation of heat becomes more and more painful, and current has to be diminished. Cure of the coryza is indicated when the patient finds it difficult to bear the treatment. Afterwards, Dr. Bordier states, the transformation is complete, and no symptom of the cold remains, except a nasal intonation of the voice, persisting for a few hours, and due to congestion of the nasal fossæ. In most cases a single sitting is enough to cure the cold, but the result is better and more complete if the patient submits to two or three.

If Dr. Bordier's experience should prove general, and if the treatment is not too painful, the method ought to become popular. But it is doubtful to what extent the good effects of the current can reach the posterior nares where in most cases the infection chiefly lies.

THE MEDICAL KING'S PRIZEMAN.

WITH 292 points out of a possible 300, Captain C. H. Vernon, late R.A.M.C., won the King's Cup at Bisley on Saturday last. It will be remembered that last year Dr. F. H. Kelly tied for first place, so that for the second year in succession the Prize goes to a member of the medical profession. Dr. Vernon is a Hampshire man and represented Oundle School (1910) and Cambridge University (1913–14) at Bisley. He served during the late war first in India and Mesopotamia as a combatant officer and later in the Royal Air Force Medical Service and the Royal Army Medical Corps. He graduated as M.B. at Cambridge in 1918 and became F.R.C.S. Edin. two years later. After resident appointments at St. Thomas's Hospital he settled in practice at Boscombe, and is now assistant surgeon and assistant obstetrician to the Royal Victoria and West Hants Hospital.

THE MENACE OF MENTAL DEFICIENCY.

THE Scottish Women Citizens' Associations are autonomous bodies which interest themselves in social reform of all kinds. The question of the permanent care of the feeble-minded has been prominent in their conferences for each of the last five years, and in 1924 they resolved to raise money for an industrial and farm colony. They were successful in arousing national interest and in collecting £12,000, and wisely handed this sum over to the Royal Scottish Institution at Larbert, the directors of which agreed to carry out the general policy of the associations. This is not the only practical step that these admirable bodies have achieved, for they have also done a great deal of sound propaganda work all over Scotland. In order to give the problem a more precise intellectual form, the Edinburgh Association have started a study circle at which many lectures have been delivered by experts in the care of the mentally defective. Seven of these lectures have been published by the Scottish Council of the associations, under the title of "The Menace of Mental Deficiency" (46, Great King-street, Edinburgh, 6*d.*), and it would be impossible to wish for a clearer and more accurate statement of the position from the scientific point of view. Dr. W. M. M'Alister writes on the distinction between deficiency and derangement and on sterilisation, Dr. R. D. Clarkson and Dr. F. A. E. Crew on heredity, Dr. Charles McNeil on the endocrine glands, Dr. C. G. A. Chislett on institutional treatment, and Dr. G. H. Henderson on the political and economic aspects of mental deficiency. The booklet therefore contains an all-round survey by a body of first-class authorities. It is clear that Scotland, thanks to the public spirit and energy of its women citizens, is facing the menace of mental deficiency.

"DERATISATION."

THE Manchester Port Sanitary Authority has officially adopted a word which has hitherto been a useful colloquialism in anti-plague work. A ship may be granted a certificate of "deratisation," when it is entirely free from rats—black rats, grey rats, brown rats—infected or uninfected with plague. The annual report states that 2344 rats were destroyed in the ships entering the port and 2656 about the dock premises, of the former 632 were in ships from plague-infected places.

GOAT KEEPING.

THE object of the British Goat Society is to encourage the keeping of goats, and the Year Book of the Society for 1927 contains a large amount of information for the general public, and useful to goat-keepers in particular. We learn that for the year ending October, 1926, British goats produced some 36,000 gallons of milk, a small quantity in view of the utility of such milk and of its comparative freedom from tubercle. Dr. G. H. T. Stovin contributes an article on the digestive organs of the goat, Mr. H. Stainton, F.R.C.V.S., discusses the benefits of light in the rearing of goats, and Dr. Anna L. Church describes "Some Goats I Have Known." Among other articles may be mentioned the future of goats' milk as pure food, the economies of goat keeping for poultry farming, the indirect profits from goat keeping, and an interesting account of "Shipwrecked Goats" in which Robinson Crusoe and Masterman Ready are not forgotten. The quality of goats in this country is steadily improving, largely owing to the lectures given under the auspices of the Ministry of Agriculture. The address of the Society is 10, Lloyd's-avenue, London, E.C. 3, where the Year Book can be obtained for the sum of 1*s.* 6*d.*

AN INDIAN DENTAL JOURNAL.

THE *Indian Dental Review*, of which the first number has just appeared from Karachi, is only the second dental journal to be produced in India, and has considerable significance as showing the development of dental science in that country. The absence of any organised system of dental education and of a Dentists' Register has heavily handicapped the development of dentistry in India, since proper training has only been possible for a small number of Indians who are able to go abroad for it. We are glad to note that the new *Review* lays stress on the need for an Indian Dental Association. It is inevitable that a journal serving such a country should depend largely on foreign contributions which have appeared elsewhere, but we trust it will not neglect the enormous field for investigation lying at its door. India, with its many races, living under different conditions, offers a peculiarly valuable field for investigating the natural history of dental disease. An inquiry into the incidence of caries and pyorrhœa and the dietetic and other factors which may play a part in predisposing or in conferring immunity to them would be of the utmost value, and might shed light on many perplexing problems. Here is an opportunity for the *Indian Dental Review*, and we hope it may be seized.

A LABORATORY ROBOT.

ALL laboratory workers who find themselves called upon to deal with large numbers of slides requiring to be stained in some one particular, develop some sort of wholesale technique of their own, but most of them must have wished for a machine which would pass the slides throughout the various steps without constant supervision. An apparatus to meet this need is now upon the market. The Sinclair Mills Auto-Immerser, once charged with slides, will carry them through all the stages of staining, rinsing, and draining, delivering them all ready for examination under the microscope. By various simple adjustments this apparatus can now be made to deal with slides to be stained either by the Gram, Ziehl-Nielsen, or Leishman techniques; for most other stains in ordinary use the further necessary adjustments could undoubtedly be devised. This apparatus should prove convenient to laboratory workers under the necessity of dealing with routine slides in large numbers. Particulars may be obtained from R. M. Catterson-Smith, Lacland-place, King's-road, Chelsea, London, S.W. 10.

THE LEPROSARIUM AT MAKOGAI.

MAKOGAI is an island north-east of Fiji, with an agreeable climate, set apart for the lepers of the Fiji Archipelago. Segregation is compulsory after certification by two European doctors, and cases may not leave the island until all clinical and bacteriological signs have been negative for two years. Hitherto both certification and transport have involved considerable delay, but the Government has now built a special vessel for leper transport only and Makogai is likely to become the leper station for the whole Southern Pacific. There are five villages, each belonging to a different nationality and governed by its own headman. The sexes are kept separate and there is a hospital for women, the helpless, and the sick. All who are fit are expected to work and to take their share in keeping the home and village clean and tidy. They have their own coöperative store. The staff consists of a medical and a lay superintendent, 12 European and eight native sisters, and an overseer. The European sisters pay daily visits to the villages and do minor dressings. The hospital is on the detached building system and has bath rooms, operating room, laboratory, and dispensary. Dr. F. Hall, who was medical superintendent of this institution from 1911 to 1920, in a little booklet describing its work writes that the prognosis is very hopeful for those who are treated early; the trouble is to get the native to report in time. Only 6 of the 444 cases discharged have had to be readmitted. The booklet is illustrated by a number of excellent photographs.

SMALL-POX AND VACCINATION.

Dr. W. McConnel Wanklyn has devoted his life to the study of small-pox, and his pamphlet on "The Accurate Diagnosis of Small-pox" (Ash and Co., Ltd., 6*d.*) has now reached a third edition. He has given numerous addresses and lectures on the subject since 1914 and he has recently brought out a revised model popular lecture entitled "To Whom it May Concern" (The Voluntary Service Fund, 36, Friday-street, E.C. 4, 1*s.* 6*d.*). In this he is at some pains to emphasise the serious nature of small-pox in the unvaccinated and his telling stories cannot fail to move an intelligent audience. One of the greatest dangers at the present time, as he points out, is that the public is getting the habit of under-estimating the enemy owing to its mild aspect. There are, he says, 30,000,000 people susceptible to small-pox in this country and exposed to the constant danger of infection from the disease as it reaches us from overseas. The intelligent audience can hardly fail to believe in the value of vaccination as a protective measure if performed in time, but after listening to Dr. Wanklyn's address it will almost certainly ask certain questions to which he has given no answer. First, is infantile vaccination absolutely necessary? Could not compulsory vaccination (without exemption) be carried out at school age, say, once on entering and again on leaving? Is it desirable to introduce what is popularly described as "poisonous material" into young infants under a month old? The author says on page 33, "the whole country is solid as to the value of vaccination in emergencies." Would not the postponement of infantile vaccination remove nearly all the objections to the practice? These are questions which intelligent men and women are constantly asking, and Dr. Wanklyn has, of course, got satisfactory answers to give. Why are his educative efforts concerned solely with preaching on a subject on which the "whole country is solid"? Would it not be better to deal with the situation as it exists in places where it is becoming the exception for babies to be vaccinated? Dr. Wanklyn writes well; his pamphlet is arresting in its clarity and manner of presentation, but it leaves the feeling that some of the main difficulties have been left untouched.

Oliver-Sharpey Lectures

ON THE

COÖRDINATION OF THE RESPIRATION AND CIRCULATION WITH VARIATIONS IN BODILY ACTIVITY.

Delivered before the Royal College of Physicians of London

BY C. G. DOUGLAS, C.M.G., *M.C.*, D.M. OXF., F.R.S.,
FELLOW OF ST. JOHN'S COLLEGE, OXFORD.

LECTURE I.

Delivered May 3rd, 1927.

THE basal metabolism of a man of normal average ize involves an oxygen consumption of about 40 c.cm. per minute, or about 200 c.cm., according o Pickworth's recent figures,[1] whilst the actual rate f oxygen consumption in an athlete who is performing trenuous exertion may be maintained for a time at value somewhat in excess of 4000 c.cm. per minute—hat is, some 17 to 20 times the basal figure. Between hese two extremes lie the figures which correspond to atural variations in bodily activity. The supply of xygen to the tissues, and the removal of CO_2 from hem, depend on the respiration and the circulation, nd in trying to ascertain how it is that these two ystems meet the demands of the tissues we cannot reat them as independent factors, for the one is ut the complement of the other. If I discuss the uestion of the breathing first it is only because a nsideration of the factors responsible for the general gulation of the circulation involves an extension of rguments primarily developed to account for the gulation of the breathing.

In thinking of increased bodily activity we are often ot unconsciously to restrict our attention to muscular ork of at least moderate severity, and here the companying changes in respiration and circulation rce themselves on our notice in the shape of panting nd increased pulse-rate. We perhaps forget for the oment how much the respiratory exchange and nergy output of the body may be altered by changes activity which we should ordinarily call trivial. hese changes may indeed appear trivial, and we may ot be sensible ourselves of any alterations in our reathing or circulation, yet there is no difficulty in roving by careful observation that there is in reality alteration in the metabolism of the body, however ight, without concomitant changes in the respiration nd circulation.

FACTORS INVOLVED IN REGULATION OF THE BREATHING.

The original paper of Haldane and Priestley [2] on e regulation of the breathing showed that the main ctor which determined the degree of activity of the spiratory centre was apparently the precise tension CO_2 in the arterial blood reaching it. A natural rollary to this is the proposition that the activity the respiratory centre is proportional to the mass of O_2 produced by the body and carried to the lungs, d we have therefore the fundamental conception at an exact quantitative correlation of the ventila-on of the lungs with the metabolism of the body as whole is brought about by chemical means.

An example of the delicacy with which the breathing correlated with small variations in the CO_2 produc-on in the body is afforded by some experiments made short time ago by Priestley and myself [3] in which we llowed in detail the behaviour of the breathing after e ingestion of a considerable quantity of sugar by person at complete rest. At the start of the periment the subject's metabolism was basal. ter the sugar had been swallowed the respiratory change and respiratory quotient soon began to rise, e maximum values being shown in about half an hour, after which the figures diminished gradually until the basal metabolism was resumed again after the lapse of two hours and a half. The rise of oxygen consumption was slight, that of the CO_2 output being considerably greater. The volume of air breathed per minute showed a perfectly definite rise and fall which ran closely parallel to the changes in CO_2 production, and the parallelism became still more obvious if the effective amount of air which actually reached the pulmonary alveoli was calculated as distinguished from the total amount of air breathed, some of which never penetrates to the part of the lungs in which respiratory interchange between blood and air occurs. The results of one of these experiments are given below.

Time.	Relative figures.		
	O_2 absorbed per minute.	CO_2 produced per minute.	Effective alveolar ventilation.
10.30	100	100	100
10.38	75 g. cane sugar ingested.		
11.7	112	141	143
11.37	110	130	134
12.7	107	122	127
12.38	98	103	109
1.8	100	101	99

The fact that CO_2 might be acting on the respiratory centre simply in virtue of its properties as an acid was suspected from the start; indeed, this point of view was definitely maintained by Haldane and myself in an explanation which we suggested to account for the changes in the breathing associated with severe muscular exercise to which I shall return in a moment, but the real justification for the view which is now held, that the respiratory centre is sensitive to changes in the hydrogen-ion concentration in the arterial blood, and that CO_2 only affects the centre in so far as it influences the hydrogen-ion concentration, was not obtained by Hasselbalch until 1912,[4] and this theory has been further confirmed in the resting subject by a study of the effects observed in experimental acidosis and alkalosis. In addition to this we have perfectly clear evidence, as a result of investigations on human subjects, that the ventilation of the lungs can also be definitely influenced by deficiency of oxygen as well as by changes in body temperature, though the stimulus afforded by deficiency of oxygen may be totally ineffective if the CO_2 pressure or hydrogen-ion concentration of the blood is sufficiently depressed. The study of the coördination of the respiration with changes in bodily activity demands therefore an inquiry into the effects of that activity on the hydrogen-ion concentration, the oxygen pressure, and the temperature of the arterial blood passing to the centre.

EFFECT OF SEVERE MUSCULAR WORK ON THE RESPIRATORY CENTRE.

In attempting to form an estimate of the degree to which these factors may be responsible for the hyperpnœa associated with increased bodily activity it is simplest to begin with the question of the hydrogen-ion concentration, as we know more about this than the other two factors, and to consider in the first instance what happens during severe muscular work. Here the picture is an exaggerated one, it is true, but this helps to render some of the facts the more obvious.

Assuming for the moment that the respiratory centre is affected only by changes in hydrogen-ion concentration in the blood, and that such changes are caused during muscular work solely by an increased rate of CO_2 production, we should expect that the hyperpnœa of muscular work would be accompanied by a rise in alveolar and arterial CO_2 pressure, and that on stopping the exercise the alveolar CO_2 pressure would return to its normal resting value as the hyperpnœa died down. Haldane, Priestley, and I were under the impression that this actually occurred

during light muscular work, but it was certainly not true if the work was so severe for the subject that he could only keep it up for a limited time. What Haldane and I [5] actually found in these circumstances was that when the work stopped the alveolar CO_2 pressure fell in the course of some minutes to a figure considerably below its normal resting value, and that the latter value was only slowly regained in the course of the next hour or so. The fact that the breathing continued in spite of this reduction of the alveolar CO_2 pressure below the normal resting value showed us that something else in addition to CO_2 pressure must be acting as a stimulus to the respiratory centre, and we suggested that the explanation was to be found in the fact that lactic acid was produced in the muscles during the severe exertion and escaped into the blood. This view was founded on a suggestion already made by Boycott and Haldane [6] to account for the influence of deficiency of oxygen, which they regarded as due to the formation of lactic acid in the tissues as a result of deficient oxidation. Subsequent investigations showed that the theory could not be maintained in the case of simple deficiency of oxygen, but it was justifiable in the case of severe muscular work, for, apart from older observations bearing on the subject, the original paper of Fletcher and Hopkins [7] on the production of lactic acid in isolated frog's muscles during anaerobic contraction, and its disappearance subsequently in the presence of oxygen, had been published two years previously. We regarded the respiratory centre as responding to what might be called the "total acidity" of the blood to which free CO_2 would contribute. If therefore lactic acid was present in the blood less free CO_2 would be required to stimulate the respiratory centre. During the severe exercise lactic acid would escape into the blood stream owing to the activity of the muscles outrunning the supply of oxygen furnished by the blood. The respiratory centre would therefore receive an excessive stimulus, for not only would the active muscles be supplying to the blood stream a far larger amount of CO_2 than during rest, but in addition lactic acid would be accumulating in the blood. The hyperpnœa during the exertion would consequently be excessive, with the result that some of the CO_2 normally held in the form of a dissociable combination in the blood and tissue fluids would be expelled. On resuming rest the blood would still be charged with lactic acid, and the alveolar CO_2 pressure would therefore be considerably lower than the normal resting value, but with the gradual elimination of the lactic acid from the blood the normal value would slowly be regained, CO_2 being retained in the body during this period to make good the amount expelled from dissociable combinations during the heavy muscular exertion.

THE RÔLE OF LACTIC ACID.

This view as we stated it now sounds crude, but nevertheless it was substantially correct. It must be remembered that it was put forward before Hasselbalch's work justified the strict statement that the respiratory centre responded to changes in the hydrogen-ion concentration of the blood, neither were the full facts known regarding the conditions governing the absorption of CO_2 by the blood, nor had the physicochemical factors governing the hydrogen-ion concentration in the blood been clearly defined. Support was given to the hypothesis when Ryffel [8] showed by analysis that great excess of lactic acid was present in the blood during severe muscular work and that the excess disappeared slowly after the work was over, and Miss Christiansen, Haldane, and I [9] proved that severe muscular work greatly reduced the capacity of the blood to combine with CO_2, the normal capacity being slowly regained during subsequent rest pari passu with the gradual resumption of the normal resting CO_2 pressure in the alveolar air.

Our knowledge in recent years has advanced rapidly. Far greater precision has been reached in our ideas regarding the hydrogen-ion concentration in the blood and the variations to which this is liable, while A. V. Hill,[10] Meyerhof, Embden, and their colleagues have raised an imposing superstructure on the foundations laid by Fletcher and Hopkins. As a result we now recognise that the immediate source of energy exhibited in a muscular contraction only involves the liberation of lactic acid from some carbohydrate precursor in the muscle, oxygen utilisation and CO_2 production being limited to a subsequent recovery process, in which a large proportion of the lactic acid is re-formed into the carbohydrate precursor by means of the energy derived from a secondary oxidation process. The extent to which lactic acid will accumulate in the active muscles and thence pass into the blood and other tissues of the body, should depend on the speed of the recovery process, which in its turn will be influenced by the availability of oxygen at the time.

This enables us to get a clearer idea of what happens when severe muscular work is done for a short time. During the work, owing to the blood stream being insufficient to satisfy the demands, the lactic acid formed in the anaerobic phase of muscular contraction cannot be compensated for sufficiently rapidly by oxidative recovery, and, as A. V. Hill, Long, and Lupton have clearly shown, not only does lactic acid accumulate in the tissues and blood—and in most surprising amount in violent exertions—but in addition an oxygen debt is incurred during the work which is only gradually repaid during subsequent rest when the oxygen-supply becomes adequate to ensure the oxidation of part of the lactic acid and the reconversion of the remainder into the precursor from which it came. The lactic acid as it is formed will combine with base derived from the salts of weaker acids; sodium bicarbonate may serve as the source of this, but Hartree and Hill [11] agree with Meyerhof in believing that a far more effective source may be found in the combination of sodium or potassium with proteins in the active tissues. The result of this buffering action is that the actual change in hydrogen-ion concentration, though large from the biological standpoint, is far smaller than might be anticipated from the amount of lactic acid formed.

THE PRODUCTION OF HYPERPNŒA.

In addition to the effect produced in this way by lactic acid accumulation we must remember that the greatly increased CO_2 production is also helping to raise the hydrogen-ion concentration in the blood, and it is not surprising therefore that panting should be violent in really severe muscular exertion. The accelerated removal of CO_2 from the body in consequence of the hyperpnœa tends to keep down the concentration of free CO_2 in the blood, and the net result of the interaction between lactic acid, sodium protein, and sodium bicarbonate will be, as Mrs. Christiansen, Haldane, and I proved and A. V. Hill has pointed out, that the amount of base available for combining with CO_2 as bicarbonate will be reduced. The respiration is therefore called upon not only to remove the CO_2 actually formed by the increased metabolic activity, but, in addition, to expel the CO_2 set free as the sodium bicarbonate concentration in the blood is diminished. So great may be the demands made on the respiration from this cause that during the exertion it may not be possible to meet them in full, and the violent panting continues for a time after the work stops, but the respiratory centre now quickly gets the better of the situation and the obvious hyperpnœa subsides.

We are accustomed to regard the hydrogen-ion concentration of the blood as proportional to the ratio of free CO_2 to bicarbonate. At the stage we have now reached, a short time after the work stops the blood and tissues are still loaded with lactic acid, for the oxidative removal of this lactic acid takes a long time. The bicarbonate concentration in the blood is still far below normal, and this in itself tends to keep the hydrogen-ion concentration of the blood above normal, but the hyperpnœa which is induced by this maintains the alveolar CO_2 pressure at a low level, and thus nearly compensates for the reduction of bicarbonate; a balance has, in fact, been struck with

he breathing slightly exaggerated owing to incomplete ompensation, though not appreciably to the subject. As the lactic acid is removed CO_2 is retained in the ody to combine with sodium as it becomes available ill the normal level of bicarbonate in the blood is e-established, the amount retained being the same as that expelled from combination during the muscular xertion. As the bicarbonate level rises in the blood he ventilation of the lungs diminishes pari passu and he alveolar CO_2 pressure and the concentration of ree CO_2 in the arterial blood increase, until finally, after the lapse of an hour to an hour and a half, the disturbance caused by the muscular work has disappeared and the normal resting conditions have been re-established.

EXPULSION OF CO_2 FROM THE BODY DURING SEVERE EXERCISE.

As I have said, Haldane and I tried to deduce the state of affairs from observations on the changes in the alveolar air, changes which affected the respiratory quotient as well as the gas pressures. Some years later I introduced a simple method by which continuous records of the total respiratory exchange could be obtained, and this made it possible to follow in detail the variations in the volume of air breathed, in the oxygen absorption, and in the CO_2 output, even in experiments involving severe muscular work. Using this method it was possible to verify our previous inferences—namely, that during severe muscular work, and for a short time after it stopped, there was an abnormally great expulsion of CO_2 from the body with a respiratory quotient well above 1·0. With the subject at rest after the exercise this high respiratory quotient soon fell to an abnormally low one, the actual rate of CO_2 production becoming disproportionally low as compared with the oxygen absorption, the return to normal or approximately normal values taking place gradually in the next hour and a half. Confirmatory evidence was thus obtained of the retention of CO_2 in the body after the exercise was over to compensate for the excess expelled from dissociable combinations during the work. Haldane, Vandell Henderson, Schneider, and I [12] obtained data of this type after severe muscular exertion at a high altitude to which we had become acclimatised, though it may be urged that the factor of reduced atmospheric oxygen pressure ought to be taken into account. This objection cannot, however, be maintained against the recent and extensive investigations of A. V. Hill, Long, and Lupton, which have afforded a more complete picture of the respiratory changes during and after muscular work.

HYDROGEN-ION CONCENTRATION IN THE BLOOD AND IN THE CELLS OF THE RESPIRATORY CENTRE.

I must, however, admit that a number of objections have been raised to the view I have just given. I suppose that most people will agree that what really determines the activity of the respiratory centre is the condition, say the hydrogen-ion concentration, actually prevailing at the moment within the cells themselves of that centre, a point upon which Gesell [13] has laid great stress in recent years. But though the hydrogen-ion concentration within the cells of the respiratory centre, whatever its precise value may be, no doubt determines its exact quantitative response, the question that immediately faces us is whether or not we are justified in inferring that changes in the hydrogen-ion concentration of the blood reaching that centre so alter the condition within its cells that we can account for the variations in the breathing that accompany changes in the activity of the body.

It by no means follows that the quantitative changes of hydrogen-ion concentration in the cells of the centre strictly conform in degree or in time relations with changes in the hydrogen-ion concentration of the blood with which it is supplied. Another factor comes into play, as Jacobs has shown,[14] and that is the differential rate at which CO_2 or undissociated H_2CO_3, the hydrogen-ion and anions may penetrate to the cell from the immediate environment of the tissue fluids or blood. It would seem that the extreme facility with which CO_2 can penetrate into the cell offers an explanation of the fact that not only the respiratory centre but also the vasomotor centre are stimulated on perfusion to a greater degree by solutions containing free CO_2 in solution than by solutions of the same hydrogen-ion concentration containing no free CO_2. The same explanation will account for the occurrence of hyperpnœa after the intravenous injection of sodium bicarbonate,[13] since the reaction between this substance and the blood proteins will cause the liberation of a certain amount of CO_2.

It is quite intelligible that in the early stage of severe muscular work the natural limitations of the respiratory muscles may hinder the ventilation of the lungs from mounting as high as would be anticipated from the rise of hydrogen-ion concentration, but Barr[15] has put forward a more difficult proposition, for he has shown that after moderately severe exercise of short duration, sufficient however to cause a marked reduction in the CO_2 carrying power of the blood, the breathing may diminish in spite of the fact that the hydrogen-ion concentration in the arterial blood is still high, if not increasing, as reckoned by the usual methods. I cannot help feeling that when changes are occurring so rapidly as they do after the stop of muscular work the explanation of this anomaly may be found in the differential permeability of the cells of the respiratory centre to CO_2 and other molecules or ions, on the lines suggested by Jacobs's work. The general theory of the relation of hydrogen-ion concentration to the activity of the respiratory centre is in harmony with so many facts that a negation of the hypothesis on the basis of certain apparent exceptions demands the most careful and detailed scrutiny before it can be accepted. Gesell adopts the sounder attitude in attempting to reason out from the available information what will happen within the cells of the respiratory centre when changes, and perhaps gross ones, occur in the arterial blood. In the long run the hydrogen-ion concentration within the cells of the respiratory centre should vary in the same sense as the hydrogen-ion concentration in the arterial blood, and in examining this question we might, I think, be wiser to study gentler muscular exercise, when equilibrium can be reached and maintained, rather than severe muscular exercise when we encounter rapid and great fluctuations in the physico-chemical conditions in the blood. All I can hope to do within the limits of this lecture is to indicate that when judged broadly the behaviour of the respiration during severe muscular work does in fact conform with the changes in reaction of the blood which we should infer from the modern conception of the lactic acid theory of the development of muscular energy.

EFFECT OF MODERATE MUSCULAR WORK ON THE RESPIRATORY CENTRE.

Let us now turn to the question of what happens when a person performs work which, though reasonably hard, can be kept up for a considerable time without fatigue. In this case there is certainly some accumulation of lactic acid in the blood, but the figure reached never approaches that found in very severe muscular exertion. Haldane and I, in our early work on the alveolar air changes resulting from prolonged exercise or cross-country running, found ourselves forced to the conclusion that a balance must fairly soon be struck between lactic acid production and its removal, and believed that whilst lactic acid was accumulating in the blood up to this equilibrium concentration a certain amount of CO_2 would be displaced from its combination as bicarbonate. Such a change would imply that the hyperpnœa would at first be considerable, but would decrease somewhat as the balance was attained and the excess CO_2 liberated from combination in the process was eliminated from the lungs. Pembrey and Cook's experiments [17] on "second wind" certainly pointed strongly in this direction. Campbell, Hobson, and I [18] also obtained further evidence supporting this view, which is in agreement with Pembrey's more
